An important shortcoming of the integrated diffusion and social network approach is that, by and large, they eschew a rigorous representation of actors' decision-making process and the feedback mechanisms that characterize the process. This weakness has been addressed by new models that seek to characterize individuals' decision-making processes as a function of individual conditions (tastes, preferences, budget constraints), the nature of individuals' social interactions (relative position in social networks, active and potential links to other actors) as well as the properties of the social groups to which the individual belongs that are affected by the adoption of the behavior. The most distinctive feature of these models is recognition and inclusion of the dynamic interplay between individuals' decision making about adoption of behaviors and the aggregate properties of the system that are influenced by those behaviors. Not only do these models acknowledge the importance of social interactions as tangible individual resources but offer room to represent the continuous reshuffling of social network connections and properties that take place as the diffusion process advances (Kohler, 1996; Brock and Durlauf, 2001; Durlauf and Walker, 1998; Durlauf and Ioannides, 2010; Lesthaeghe and Vanderhoeft, 2001).

Agent-Based Models

The formulation of social interaction models to represent diffusion processes is a significant departure from and improvement upon more traditional approaches but comes with a steep price tag: the empirical estimation of key parameters from observables can only be carried out after considerable simplifications. While these models allow a richer formulation of diffusion of behaviors, empirical estimation requires the translation of complex models into stylized and oftentimes confining representations. An undesirable outcome of this is that the mismatch between empirical findings and theoretical expectations lends itself to ambiguous interpretations: it can be due not only to the formulation of a faulty model but also to a faulty translation of the original to the estimable model.

Agent-based models provide a solution to the conundrum. While these models are a very general tool to handle complexity and were not formulated to study diffusion process, they can be hijacked to represent some of the most complicated features of diffusion phenomena. Agent-based models are designed to include as much complexity contained in the individuals' decision-making processes as the researcher considers necessary; they are ideally suited to incorporate alternative feedback mechanisms that capture the dynamic interplay between individuals' decisions and the properties of the collective or aggregate.

An agent-based model consists of a set of rules that generate individual behaviors as well as aggregate properties. These rules are translated into 'observables' via computer simulations that keep track of individual actors, their characteristics and relations to other actors in the system, and the evolution of the social contexts within which those individuals interact. Agent-based models lead to precise predictions about aggregate characteristics of a collection of actors that can be readily contrasted with observed outcomes to decide about the accuracy of the original model(s).

In social sciences the best-known ancestors of agent-based models are microsimulation models of population dynamics (Sheps and Menken, 1974; Bongaarts, 1981; Wachter et al., 1979; Palloni, 1996). So far the bulk of modern agent-based models have been deployed in epidemiology and population health (Auchincloss and Diez-Roux, 2008) but there are clear indications that their use is spreading and catching on elsewhere in sociology and demography (Centola, 2010; Macy and Willer, 2002; Billari et al., 2006; Axelrod, 1997a,b). While none of the applications to date are explicitly designed to deal with diffusion processes, the extension is not complicated and one could easily imagine how diffusion models that include the complexity implied by social interactions and network models could lead to standard agent-based models.

Future developments of diffusion models are likely to proceed via the agent-based model route, thus fulfilling the promise of a sociological tradition that foresaw the need to incorporate for complexity but could not quite consider it explicitly.

This article is a revision of the previous edition article by A.S. Kaye, volume 6, pp. 3688–3691, © 2001, Elsevier Ltd.

Abstract

The article reviews the basic literature on diglossia with special reference to its linguistic and social features. A number of diglossic cases are discussed with special emphasis on diglossia in the Greek-speaking world, the Arab-speaking world, and Switzerland. The main argument put forward is that as it currently stands the term 'diglossia' does not do justice to the peculiarities found in the various contexts of diglossia.

One of the basic features of every multilingual society, which nowadays is the rule rather than the exception all over the world, is the coexistence of various linguistic codes or varieties, which are usually associated with specific contexts of use, situations, or discussion topics. The coexistence of two linguistic varieties, each of which performs different social functions and is associated with different ideologies, came to be known as 'diglossia.' The term is inseparably linked with Charles Ferguson and his seminal 1959 article, which essentially introduced the term 'diglossia' into the sociolinguistic paradigm. Since Ferguson was the first to describe this phenomenon in a systematic way, his definition is considered to be the classic version, especially in view of the later modifications to the concept proposed by Joshua Fishman (1967).

Charles Ferguson has summarized diglossia as follows (1959: 245):

> Diglossia is a relatively stable language situation in which, in addition, to the primary dialects of the language (which may include a standard or regional standards), there is a very divergent, highly codified (often grammatically more complex) superposed variety, the vehicle of a large and respected body of written literature, either of an earlier period or in another speech community, which is learned largely by formal education and is used for most written and formal spoken purposes but is not used by any sector of the community for ordinary conversation.

In light of the above, diglossia translates into the simultaneous use of two varieties, one of high value (henceforth H) and one of low value (henceforth L). Fishman (1967) argued that diglossia could be extended to situations where forms of two genetically unrelated (or at least historically distant) languages occupy the H and L niches, such that one of the varieties, the H, is used for religious, educational, literacy, and other such prestigious domains, while the other one, L, is only employed for more informal, primarily spoken domains. The difference between the two is captured in the following quote: "H and L have disjoint functions: where H is appropriate, L is inappropriate and vice versa" (Sebba, 2011: 450). It thus becomes evident that the difference between the two is not only linguistic but also social, since the use of the two varieties is associated with different social functions, styles, and registers. It is noteworthy, however, that H and L are not separate languages, but varieties of the same language.

Diglossia has been claimed to be an Oriental phenomenon, as it was found in Arabic, Chinese, Sanskrit, as well as Greek (Psycharis, 1902: 129, 155, as cited in Mackridge, 2009: 27). Nonetheless, it is also found in other Western contexts. In light of this, the four most common examples of diglossia that have been discussed in the literature include the Greek-speaking world, where diglossia used to exist as the H variety called katharevousa (pure), and the L variety called dhimotiki (people's language) till 1976 (Frangoudaki, 1992; Mackridge, 2009), the ongoing diglossia in the Arab-speaking world, where there is al fusha (Modern Standard Arabic henceforth MSA) as the H variety and al ammiyya (Arabic dialect varying according to the country where it is spoken) as the L variety (Bassiouney, 2009; Stadlbauer, 2010), the diglossia in Switzerland with Hochdeutsch (High or Standard German) and Schwyzertüütsch (Swiss German) as L (Hogg et al., 1984; Stepkowska, 2012), and finally Haiti with French as H and Haitian Creole as L (Valdman, 1988). As will become clear below, apart from these contexts, diglossia is a vital phenomenon embedded in the general field of societal multilingualism all over the world. As such, it falls under the macrolevel of sociolinguistics since it is a phenomenon relating more to a social group rather than an individual. The attempts at a classification of the original concept and the multitude of interpretations, prove the intense interest diglossia has triggered among (socio)linguists.

Classificatory Schemes

Ferguson (1959) and Fishman (1980) have been talking about 'classical diglossia,' namely a state of affairs, where H is seen as classical and L as vernacular, and between them there may or may not be a genetic relation. Examples of the former include classical and vernacular Arabic, classical or classicized Greek (katharevousa) and vernacular Greek (dhimotiki), classical and vernacular Tamil, classical and vernacular Sinhalese, Sanskrit and Hindi, or classical Mandarin and modern Pekinese. An example of classical diglossia where H and L are not genetically related is Yiddish and Loshn koydesh (Aramaic, i.e., textual Hebrew), as discussed in Fishman (1976).

Apart from classical diglossia, where there is usually close connection between the two varieties, there is also 'extended diglossia' (Fishman, 1967), namely the coexistence of H and L

varieties, where the relationship between the two is distant. An example of extended diglossia is the use of Spanish and Guarani in Paraguay (Rubin, 1972).

The distinction between classical and extended diglossia has been labeled differently by various other scholars: narrow and broad diglossia (Scotton, 1986), use-oriented or diatypical, and user-oriented or dialectical (Britto, 1986).

Except for the distinction between classical and extended diglossia, Fishman usefully distinguishes between written/formal-spoken. Examples of such a type of diglossia include Standard German and Swiss German, standard spoken Pekinese [Putonghua] and Cantonese, Standard English and Carribean Creole (Fishman, 1980: 4). An example of diglossia, which does not fall neatly under any of the two classification schemes but which can be seen as combining features from both is Tamil. This language has three norms (a classical, i.e., Sangam or Pandit style, modern literary/formal-spoken, and educated colloquial) and a number of local dialects. Between these styles there are shadings from one style into another, i.e., it is possible to write modern Literary Tamil with an archaic lexicon but with nonarchaic grammar; it is also possible to swing in the other direction and make modern Literary Tamil more spoken, or to make educated colloquial more literary in flavor, or more nonstandardly colloquial (Schiffman, 1997: 210).

Despite these artificial distinctions between different types of diglossia, it would be fair to say that diglossia can be better seen as a continuum, in the sense that the boundaries between the H and the L are not sharp. In the literature of diglossia seen as a continuum, various other categorizations of the phenomenon have been proposed.

Partial versus Total Diglossia

The distinction between the two, made by Schiffman (1997: 212), is related to the overall number of users of either of the two varieties (H and L) or each and one of them. It has been observed that in some societies speakers know H, but others have L as a mother tongue and learn H as a second language. In this way, in some societies, all speakers exhibit diglossic behavior (i.e., use both H and L varieties in complementary distribution), while in others, only some members of the society do so. This could be illustrated either by a society where everyone speaks L, but only some are actively fluent in H, or the opposite case where everyone speaks and writes H, but some also master an L variety.

Homogeneous and Heterogeneous Diglossia

Another aspect of diglossia, which needs to be discussed is whether the L norm is in fact one variety or more than one, i.e., whether it is homogeneous or heterogeneous. That is, is there an L variety that can be used for communication throughout the linguistic culture and with all segments of the speech community, such that no one is forced to resort to the H variety (written/formal-spoken) or some other language, as a lingua franca. In Switzerland, no L variety is recognized as standard; speakers must learn to accommodate their variety to those of others, since the use of H Schriftdeutsch is not considered appropriate between Swiss citizens (Schiffman, 1997: 213). Another example of heterogeneous diglossia is the Arab world, where due to the diverse countries belonging to the Arab world spanning from Morocco to Yemen, no one L variety is recognized as standard either and some times native speakers of Arabic, e.g., a Moroccan with a Saudi, switch to English instead of MSA, in order for their communication to be facilitated.

Overall, though linguistic cultures think of diglossia as either-or, it is often a gradient cline, with one variant blending into another one. This becomes evident in, for example, Tamil, where the distribution of domains reserved for each variety or other can vary: in Tamil the political speech was once restricted to the domain of the H variety, but nowadays contains style-shifting, evident in the use of the H variety in the beginnings and closings of political speeches, while in the middle of the speeches the L variety is used, most probably for reasons having to do with the establishment of solidarity and rapport between the politician and their audience (Schiffman, 1997).

Regardless of how it is classified, diglossia is a sociolinguistic phenomenon involving its own peculiar linguistic and social features associated with each of its varieties. These features are further discussed in the following two sections.

Linguistic Features of Diglossia

In terms of the two varieties' linguistic systems, Ferguson has identified a typology of differences between H and L. First of all, in terms of their respective grammar systems, there are extensive differences in terms of grammatical complexity: H has grammatical categories not present in L and has an inflectional system of nouns and verbs which is much reduced or totally absent in L (Ferguson, 1959: 241). For example, Swiss German has three cases (nominative, dative, and accusative) in the noun and only one simple indicative tense, while Standard German (Hochdeutsch) inflects nouns, adjectives, and pronouns into four cases (nominative, genitive, dative, accusative) and has two nonperiphrastic indicative tenses in the verb. Likewise, katharevousa has four cases, while dhimotiki has three (it does not have dative). Similarly, Classical Arabic (CA) has three cases in the noun, marked by suffixes, i.e., word endings, while colloquial dialects have none. Finally, in the case of Haiti, French has gender and number in the noun, whereas the Creole has none.

Overall, Ferguson (1959: 241–242) has proposed a 'rule of diglossia,' according to which "the grammatical structure of language A is simpler than that of B if, other things being equal,

1. The morphophonemics of A is simpler, i.e., morphemes have fewer alternants, alternation is more regular.
2. There are fewer obligatory categories marked by morphemes or concord.
3. Paradigms are more symmetrical.
4. Concord and rection are stricter."

Provided one agrees with the aforementioned take on grammatical simplicity, one can argue that the L variety in Arabic, Greek, and Haitian falls under the category of a 'simplified' grammatical system, because it not only has simpler morphophonemics (e.g., in dhimotiki the marking of plural in nouns is simpler than that of katharevousa), but it also has fewer obligatory categories (e.g., the L variety of Arabic

does not use the dual, which exists and is used in the H variety) and the concord and rection are stricter (e.g., prepositions all take the same case in Haitian Creole rather than different as in the case of French), a fact that leads to greater symmetry in the paradigm of L than that of H. The only language that does not seem to align with the morphophonemic simplicity of its system is Swiss German, which despite its L status, has more complex morphophonemic structures than Standard German (Ferguson, 1959: 242). The idea that L does not always have to have grammatical simplicity was picked up by Fasold, who claimed that scholarship tends to "attribute simplicity to the grammar of L from pure intuition and not from systematic observation" (1987: 37).

In terms of vocabulary, despite the fact that the bulk of lexicon is shared between H and L, H is characterized by "technical terms and learned expressions, which have no regular L equivalents" (Ferguson, 1959: 242). More specifically, it is usually the case that between H and L we have the existence of paired items, one H and one L, which are used in different registers, i.e., levels of talk, ranging from formal (H) to informal (L). Examples of such pairs include the following ones:

Greek

H	*L*	*Translation*
idria	stamna	Urn, jug
idor	nero	Water
sarothro	skoupa	Broom
klini	krevati	Bed

Arabic

H	*L (Qatari dialect)*	*Translation*
keyfa haluki? (fem.sg.)	akhbarich?	How are you?
ayna anti? (fem. sg.)	wainich?	Where are you?
haqan?	sejj?	Really?
la a'aref	madri	I do not know

Haitian Creole (Taken from Ferguson, 1959: 243)

H	*L*	*Translation*
homme, gens	moun	Person, people
âne	bourik	Donkey
maintenant	kounyea	Now
donner	bay	Give

Such pairs are difficult to be found in Swiss German, because in that variety the phonological differences between H and L are extensive and the normal form of lexical pairing is regular cognation (e.g., *klein* in Standard German becomes *chly* 'small' in L) (Ferguson, 1959: 243).

At the level of phonology, there seems to be variation in the grade of similarity between the phonological systems of H and L in the aforementioned languages; while in Greek the systems are very close, in Arabic and Haitian they are different and in Swiss German they are very different. Ferguson has come up with two descriptive phonological rules, which account for the differences between H and L (1959: 244):

1. The sound systems of H and L share the same phonological structure of which the L phonology is the basic system and the divergent features of H phonology are either a subsystem or a parasystem. In this way, H has a more complex morphophonemics.
2. If 'pure' H items have phonemes not found in 'pure' L items, L phonemes frequently substitute for these in oral use of H and regularly replace them in borrowed elements by using the H-variety contrast in that particular item. Such a widely cited example is the use of the front rounded vowel /ü/ in French, which however is not used in Haitian Creole. Hence, when Haitian speakers want to sound educated, they would pronounce the word Luke as /lük/ in the context of the Gospel of St. Luke. Nonetheless, in the Haitian Creole, they would use the phoneme /i/ instead of the front rounded one /ü/ (1959).

Social Features of Diglossia

As a sociolinguistic phenomenon, diglossia should be understood in the context of the society in which it exists. The most important social feature is the function of diglossia.

According to Ferguson (1959: 236), H is used primarily on the following occasions or it performs the following functions:

1. sermon in places of worship (e.g., church, synagogue, or mosque),
2. speech in parliament,
3. personal letters,
4. university lectures,
5. news broadcasts,
6. news editorials, news stories, captions on pictures, and
7. poetry.

On the other hand, L is used in:

1. instructions to servants, waiters and waitresses, workforce and clerks,
2. conversation with family, friends, and colleagues,
3. TV soap operas,
4. captions on political cartoons, and
5. folk literature.

Even though this is a useful typology of social functions, the reality is somewhat more complex. For example, in the context of formal education the use of different varieties is not as rigid as implied in the typology, inasmuch as in countries like Greece (until 1976) and in the Arab-speaking countries (till nowadays) university lectures take place in H, but explanations of drills or answers to students' questions may be conducted in L. Poetry is also tricky as a context, because in countries like Greece, written poetry was written primarily in the L variety, as the use of H was considered to be artificial. On the other hand, in the Arab

world several fixed polite expressions or proverbs are in H, despite the fact that sometimes they are used by illiterates (Ferguson, 1959: 237).

Power and prestige are two other very important social factors that have a bearing on how diglossia operates within a given society, even though it has been noted that they have not been delved into (Sebba, 2011). H is usually rated more highly than L, for the simple reason that the former is used in formal contexts, associated with prestige, such as religious or educational settings, while the latter is used for more informal and hence less prestigious functions, such as everyday discussions. Such a distinction is very evident in the Arab world, where H (CA in particular) is usually associated with beauty, impeccability, elegance, and eloquence, because it is seen as stemming directly from Allah, while the various L varieties are felt to be less worthy and, hence, reserved for functional purposes only. Such state of affairs also leads to differences in the respective acquisition of the two varieties: while L is acquired first as the language spoken at home serving everyday, mundane communicative purposes, H is learned at school. As a result of this, H is highly standardized, namely it is codified in dictionaries, grammars, spelling guides, and canonical texts, to mention just a handful. Finally, diglossia in general can be seen as a stable phenomenon, persisting for centuries or even millennia (Schiffman, 1997: 207). Occasionally, L varieties gain domains and communicative functions and, hence, displace the H variety. Nonetheless, the other way round is possible as well, namely the H variety can displace L, only if H is the mother tongue of an elite (Schiffman, 1997). To illustrate the first case, namely the substitution of H by L, diglossia in the Greek-speaking world will be discussed. Then, diglossia as a stable phenomenon will be discussed on the basis of the Arab-speaking world.

Diglossia in the Greek-Speaking World

In the Greek-speaking world we have a sense of linguistic continuity throughout history. Because Ancient Greek did not split into several distinct modern languages, the modern Greeks can see themselves as the sole possessors and guardians of the diachronic Greek language from Homer to the present day. This sense of the continuity of the popular language and culture since antiquity was offered to the Greeks by the demotic movement, namely the effort on behalf of a number of Greek scholars to establish dhimotiki as the official language of the state on the grounds of its association with naturalness and unique ability to express emotions. It was this movement that made Greeks realized that dhimotiki was not a corrupt form of Hellenic language, the term used to refer to the Greek language in its diachronic presence, but it was Hellenic, and thus equivalent to katharevousa ('pure,' educated people's variety).

Diglossia is a term coined by the Greek novelist and essayist Emmanouil Roidis in 1885 and used by Yiannis Psycharis, an advocate of dhimotiki (Mackridge, 2009: 27), the L variety of Greek diglossia. In the context of Greece, this term denotes the use of two lexical and grammatically distinct varieties of Greek on behalf of the same users but in different circumstances. The distinction between the two varieties, namely katharevousa (the H variety) and dhimotiki (the low variety) is made not only on the basis of the medium (written vs oral language) or the level of educatedness of the users, but also on the basis of the level of formality of speech. In fact, it covers a continuum of linguistic registers ranging from 'pure' dhimotiki to 'extreme' katharevousa with hybrid varieties in between (Mackridge, 2009: 29).

Diglossia spans across all levels of linguistic description. Below are found some examples, which illustrate this:

Phonology: Katharevousa – 'anðras' (man) – Dhimotiki – 'andras' (man)
Morphology: Katharevousa – 'vasilisis' (GEN. queen) – Dhimotiki 'vasilisas' (GEN. queen)
Syntax: Katharevousa – 'i proanaferθisa omilitria' (the aforementioned speaker) using the aorist passive participle – Dhimotiki 'i omilitria pou molis anefera' (the speaker that I just mentioned) using a secondary pou clause.
Semantics: Katharevousa – 'katalavo' (occupy) – Dhimotiki – 'katalavo' (understand).
Vocabulary: Katharevousa – 'inos' (wine) – Dhimotiki 'krasi' (wine)

From 1880 to 1976 many Greek novelists were diglossic in their writing; for example, in his capacity as general secretary of the University of Athens, the demoticist poet (i.e., he wrote poetry in dhimotiki) Kostis Palamas drew up official documents in impeccable katharevousa. Along the same lines, Giorgos Seferis wrote in katharevousa as a diplomat and civil servant, while all of his literary writings are in dhimotiki. Until 1976, the year when katharevousa was abolished in Greece, all educated Greeks had been taught Ancient Greek at school. Today, Greek churchgoers are used to listening to archaic (koiné) Greek being chanted and recited. It is very important to highlight that, from a descriptive linguistic perspective, these two varieties have influenced each other and, hence, shape people's (hybrid) sociolinguistic choices, but sometimes for people themselves these two varieties may not have such sharp social meaning distinctions. This idea is captured nicely in Margaret Alexiou's words that "the two forms (katharevousa and dhimotiki) interpenetrate continuously, yet exclude each other consciously" (1982: 178).

The descriptive adequacy of the term diglossia to capture the gist of the linguistic complexity of Greece has been criticized in the literature for its oversimplification and its subsequent inability to do justice to the description of hybrid varieties found in (contemporary) Greece (e.g., Drettas, 1981; Alexiou, 1982; Kazazis, 1993; Holton, 2002). In addition, dhimotiki has been claimed to be "a codified and normalized form of the 'natural' language" (Frangoudaki, 1992: 360). Seen like this, dhimotiki, namely the L variety of Greek diglossia, is a written language. This runs contrary to Ferguson's point that the L variety is neither written nor standardized. Similarly, katharevousa is not only a hybrid consisting of lexical and grammatical features belonging to different historical stages of spoken Greek from Classical times to the present day but it was also used by different authors differently, i.e., in the proportions and the categories of the archaic features (Mackridge, 2009: 30).

Another way, in which Greek has been claimed not to fall under the term 'diglossia' is through the status of dhimotiki itself. More specifically, dhimotiki had been planned as a written language from the late nineteenth century onward, a state of affairs that led the challenging of the *de jure* monopolistic privilege of katharevousa to be thought of as the H variety (Mackridge, 2009). As a result of this, katharevousa alone was the official language of the state from 1911 to 1976, and dhimotiki along from then onward.

In the other country, where Greek is the official language, Cyprus, the situation with diglossia is different. There, since independence in 1960, the Greek Cypriots have fitted the Fergusonian model of diglossic community more closely than the Greeks of Greece. The reason for this is because, even though the official language of the country, along with Turkish is exactly the same as in Greece (katharevousa until 1976, dhimotiki since then) and most writing and official oral communication is carried out in standard Greek, Greek Cypriots speak among themselves informally in Cypriot Greek, which is markedly different from the standard written variety and is not normally used even in literature, except when recording or imitating folk poetry or for comic purposes (Karoulla-Vrikki, 2005: 13–14, as cited in Mackridge, 2009: 31).

In conclusion, even though Cyprus seems to be characterized by a more clear-cut diglossia, in Greece diglossia is not very transparent precisely due to the presence and use of uncodified, unstable, and intermediate forms of the language, which are to be found even nowadays in both written and oral genres of speech (e.g., in political discourse both inside and outside the Parliament, in computer-mediated communication, to mention just a handful of examples). Finally, it is worth mentioning that the existence of such mixed form of language (Greek mikti) has been already acknowledged by Ferguson himself (1959: 240). It was in the later scholarship that this idea was further developed and illustrated through concrete (socio)linguistic examples.

From the substitution of H by L and the abolition of diglossia in the Greek-speaking world, the discussion now shifts to an example of stable diglossia, which has been persistent throughout the years, namely the one still found in the Arab world.

Diglossia in the Arab-Speaking World

In the Western scholarship, Arabic is usually used to illustrate diglossia through reference to the distinction between MSA (al fusha) and the local or colloquial dialect (al ammiyya), which differs in terms of its phonetics, semantics, and vocabulary from country to country. An example of a phonetic difference found in different dialects is the use of the sound [g] instead of the standard [j] in Egyptian, Sudanese, and a number of Saudi Arabic dialects, which are spoken in areas in Saudi Arabia close to Egypt. Likewise, in terms of semantics there are differences between different dialects as well; for example, the wish 'bel afia' means something like enjoy your meal or bon appétit in the Gulf, but it is used as a swear word in Moroccan dialect. Likewise, in terms of vocabulary there are differences as well: 'how' is 'izzay' in Egyptian Arabic, but 'kayf' in MSA. 'Where' is 'fayn' in Egyptian Arabic, but 'eyen' in MSA.

If the concept of diglossia is contested in the Greek-speaking world, it is highly problematic in the Arab-speaking world. The main reason behind this is not only the wide sociolinguistic variation, i.e., the existence and use of a great number of different regional and social dialects spoken in the 22 countries, which form the Arab League, but also because the distinction between MSA and CA, the language of the Holy Qur'an, is not always clear.

It has been proposed that the distinction between MSA and CA is a western invention, in the sense that there is no Arabic term to capture it (Bassiouney, 2009: 11). Nonetheless, the two varieties are used on different occasions: while MSA is used in political and any sort of public formal speech, CA is used primarily as a religious language, i.e., as the language of recitation of the Holy Qur'an and quotation of classical texts. According to Ryding (2005: 7), both varieties are referred to as 'al loga al fusha' (literally 'literate language'). While what they share is more than what differentiates them, the main differences between the two are at the level of lexis and style rather than the level of grammar. MSA can be seen as simpler and more flexible than CA, inasmuch as it has a more relaxed word order, evident primarily in journalistic style, as well as the capacity of coining neologisms and borrowing terms or getting loan translations from other languages, primarily western ones. As a result of these tendencies, MSA's lexicon has a more modern vocabulary (primarily for technology) than CA and a style that has been influenced by other languages.

Arabic scholarship prefers to view diglossia in the Arabic world as gradable or leveled diglossia; what this means is that the phenomenon of diglossia in the Arab world is explained in terms of different levels of the spoken language. Early scholarship focusing on the analysis of cross-dialectal conversational data (Blanc, 1960: 85, cited in Bassiouney, 2009: 14) has claimed that there are five varieties of Arabic: classical, modified classical, semiliterary or elevated colloquial, koineised colloquial, and plain colloquial. Later scholarship identified other categorizations based on the degree of educatedness associated with the varieties; along those lines Meiseles (1980) has identified four varieties: literary Arabic or standard Arabic (the language used in written literature), oral literary Arabic, educated spoken Arabic, and plain vernacular. In a similar vain, Badawi's (1973, as cited in Bassiouney, 2009: 15) distinction among five levels of Arabic, after he analyzed data from Egyptian media, can be seen as more complex than the other two, inasmuch as it blends in both stylistic and social factors associated with the uses and users of the varieties. The five varieties or levels are the following ones: heritage classical (fusha: al- tura:θ), which is equivalent to CA, namely the variety used in the Holy Qur'an and CA literature, contemporary classical (fusha: al-'asr), the equivalent to MSA, colloquial of the cultured ('a:mmiyyat al-muθaqqafi:n), an oral variety used for serious discussions and university lectures, the colloquial of the basically educated ('a:mmiyyat al mutanawwiri:n), namely an oral variety used in discussion of nonintellectual topics, and finally the colloquial of the illiterates ('a:mmiyyat al-'ummiyi:n), a variety characterized

by a simplified linguistic structure and used in the mouths of bad characters in soap operas, and sometimes in comic situations.

Diglossia in Switzerland

Switzerland, with 74% of its speakers being German-speaking (Clyne, 1984: 18), is another example of diglossia mentioned by Ferguson (1959). Compared to the previous two cases, however, it has received relatively little analytical attention (Stepkowska, 2012: 206). For centuries the country has maintained a balance between Swiss German or Schwyzertüütsch or L (i.e., an umbrella term for several Alemannic dialects that developed around the largest Swiss cities without any 'standard' Swiss German, although, see Thuleen, 1991) and Standard German or H, to the point where the fusion between the two has been permanently averted (Martinet, 1986: 248). In fact, diglossia has proved useful to the German-speaking Swiss. First of all, the Swiss diglossia has counterbalanced the pressure exerted by the neighboring powerful German-speaking states by acting as a distinguishing marker of the countries to the north and south of the Rhine. In this sense, Swiss German or L can be seen as having political significance for the country. In addition, Swiss German can be also seen as a solidarity marker, which has helped to preserve the independence of the country and its distinctiveness from neighboring Germany. This distinguishing feature, the vernacular, was particularly important during the years of Nazi government in the Third Reich. It was at that time that Swiss Germans sought refuge within their own language. It was also at that time that Swiss German entered many spheres of public life, never to lose its position. Today, Swiss Germans assert their independence from Germans in the same way – through their own distinctive spoken L variety in which they take pride (Stepkowska, 2012: 202).

Furthermore, diglossia in Switzerland is further stabilized due to the country's strong constitutional protection for all official languages (German, French, Italian, and Romansh). Standard German is taught at schools and used in the media, literature, and most official situations, thereby providing Swiss Germans with access to the outside world through Standard German, written or spoken. Lastly, it may be said that Swiss German is an instrument of practical democracy. Due to its common use, it does not divide society into classes as in many other countries, but it unites people.

In the literature on Swiss German it has been suggested that each German-speaking Swiss canton may be regarded as a bilingual-diglossic speech community, where people use Swiss German and Standard German in a typically diglossic manner (Fasold, 1984: 41). In order to highlight the difference between the Alemannic dialect and Standard German, the former was referred to as Eidgenossisch/Helvetisch Landsprach, Schwyzerisch, der Helvetier Tütsch, and also since 1750 as Schweizerdeutsch or Schwyzertüütsch (Stepkowska, 2012: 203).

The main differences between Swiss German and Standard German are to be found in all levels of linguistic analysis (for a comprehensive discussion and detailed examples, see Thuleen, 1991).

Below are given indicative examples of differences at the levels of vocabulary, morphology, and phonetics/phonology (all examples are taken from Thuleen (1991)):

Vocabulary

Swiss German	*Standard German*	*English translation*
die Serviertochter	die Kellnerin	Waitress
der Spital	das Krankenhaus	Hospital
der Camion	der Lastkraftwagen	Truck
das Postbureau	das Postamt	Post office
der Kondukteur	der Schaffner	Train conductor

Morphology

The morphological system of numerals in Swiss German is more complex than in Standard German, inasmuch as there are more types in the former according to the grammatical gender, while in Standard German there is only one type used for all genders (zwei [two], drei [three]):

Case	*Masculine*	*Feminine*	*Neuter*
Common case	Zwee	Zwoo	Zwäi
	Drei	Drei	Drüü
Dative case	Zweene(n)	Zwoone(n)	Zwäine(n)
	Dreine(n)	Dreine(n)	Drüüne(n)

Such examples from Swiss German cast into doubt Ferguson's aforementioned claim about L being simpler linguistically than H.

Phonetics/Phonology

In Swiss German, the Standard German phoneme /k/ is almost always realized as [x], and is often spelled as ch. Thus, the consonant cluster /nk/ is realized as [nkx]. There is no counterpart to the velar fricative [x]; this means that the suffix -ig is not pronounced as [iç], like in Standard German, but rather as [ix] or, in some cases, as [ig].

Overall, it must be stated that, like in the case of Greek-speaking and Arab-speaking worlds, diglossia is a highly contested notion in the context of Switzerland exactly because of its at times inaccurate descriptiveness.

Conclusion

Despite the H and L varieties' clearly demarcated linguistic features and domains of use, diglossia is a gradient, variable phenomenon, which cannot easily be narrowed down to an either-or, binary system of categorization. The sociolinguistic complexities that have been discussed on the basis of diglossic examples from the Arab world, Haiti, Greece, and Switzerland have shown clearly that the concept of diglossia needs to be further theorized, in order to do justice to the peculiarities of the various instances of this sociolinguistic phenomenon.

Dilthey, Wilhelm (1833–1911)

Timothy D Mooney, School of Philosophy, University College Dublin, Dublin, Ireland

© 2015 Elsevier Ltd. All rights reserved.

Abstract

A pivotal influence on modern European philosophies of interpretation and existence, Dilthey differentiates the human sciences of understanding from the natural sciences of explanation. He explicates life as a flow of lived experience and as an individual and sociohistorical nexus of knowing, feeling, and willing. In his middle period, he sees descriptive psychology as the foundational approach for understanding lived experience, but subsequently emphasizes the hermeneutics or systematic interpretation of outer expressions of life, from politics and law to literature and architecture. His insights into the temporality, historicity, and finitude of life are developed further in his philosophy of worldviews.

Though he was known as 'the man of first volumes' and never brought his life's great project to completion, Dilthey was a pivotal influence on the development of European philosophies of interpretation and human existence in the twentieth century, and his views of historicity, lived experience, expressivity, and understanding have been no less important than the accounts of description and hermeneutics with which they are interwoven. Wilhelm Christian Ludwig Dilthey was born in Biebrich am Rhein near Wiesbaden on 19 November 1833. He completed his Gymnasium education in 1852, and studied theology and philosophy for several semesters at Heidelberg. He moved to Berlin in 1853, working in philosophy, classics, and philology under former students of Friedrich Schleiermacher (1738–1834), and in history under the university's leading historians. Following his state exams in 1856, Dilthey taught for a short time in two Gymnasiums. In 1859 he was invited to work on the publication of Schleiermacher's letters, and in 1860 won an essay competition for 'A Comparison of Schleiermacher's Hermeneutics to the Earlier Systems of Protestant Hermeneutics.' Dilthey gained his doctorate from Berlin in 1864 for a thesis on Schleiermacher's ethics. He was appointed as a professor of philosophy at Basel in 1867. Two years later, he was appointed to the chair of philosophy in Kiel, and then to the Breslau in 1871. In 1874 he married Katherine Puttmann, and they had two daughters and one son. Dilthey was appointed to the prestigious chair of philosophy in Berlin in 1882 and retired in 1905. Productive to the last, he died unexpectedly on 1 October 1911. The cause was the outbreak of an infection in Seis am Schlern in South Tyrol, where he was on a working holiday.

Dilthey achieved widespread acclaim in Germany in 1870, when the first and only part of his *Life of Schleiermacher* was published. The year 1883 saw the publication of the first part of his projected *magnum opus*, the Critique of Historical Reason. Comprising two books, this part was entitled *Introduction to the Human Sciences*. A second part made up of four and then five books was planned, but this was never completed. The next phase of his thought is to be found in *The Origin of Our Belief in the Reality of the External World and Its Justification* from 1890, and *Ideas for a Descriptive and Analytic Psychology*, from 1894. The beginning of the last phase of his intellectual development was flagged in the 1900 article 'The Rise of Hermeneutics.' In 1905 he published *Lived Experience and Poetry*, in 1906 *The Young Hegel*, and in 1907 *The Essence of Philosophy*. The year 1910 saw the appearance of *The Formation of the Historical World in the Human Sciences*, a continuation and reworking of the Critique project, and 1911 *The Types of Worldview and Their Development in Metaphysical Systems*. A further volume of *The Formation* was also planned, the notes for which are found in the posthumous *Drafts for a Critique of Historical Reason*.

The Human Sciences, Lived Experience, and Psychology

The central task of the Critique as announced in the *Introduction* was to provide an epistemological foundation for what Dilthey called the human sciences. This required the explication of the human being's capacity to know itself and the society and history that it has produced. Though well cognizant of the historical character of human existence brought out by Giambattista Vico (1668–1744) and G.W.F. Hegel (1770–1831), Dilthey regarded his Critique as complementing, above all, Kant's critical epistemology of the natural sciences. It would also incorporate the modes of aesthetic and teleological experience set out by the earlier thinker, while bringing out the dynamically living preconditions of the critical philosophy itself. Such a reconstructed critical approach was intended to transcend both Kantian formalism and the speculative excesses of Hegelian idealism. To critique historical reason is to show that there are manifold meanings in history, but no unitary significance underlying it, no trajectory toward the fables of a promised land or absolute knowledge. In this early phase, Dilthey already distinguishes between the natural and the human sciences and between explanation (*Erklärung*) and understanding (*Verstehen*).

Outer nature is the concern of the natural sciences, and they explain natural or physical phenomena in terms of efficient causes. They begin with the identification of certain classes of phenomenal objects and of their regularities and seek to enumerate their elementary constituents and the causal relations holding between them. Essential to the explanatory procedure of these mathematical and quantitative sciences are hypothetical generalizations that go beyond empirical phenomena. If a hypothesis passes a wide range of experiments and has predictive worth, it is accorded the status of a scientific

 http://dx.doi.org/10.1016/B978-0-08-097086-8.61189-3

theory positing an atemporal law of nature. Despite the exact character of the natural sciences, Dilthey regards the truth of their theories as provisional. They have instrumental and probabilistic worth, and may be deposed in future. Such an account anticipates, in part, Karl Popper's (1902–94) falsificationist philosophy of science (Krausser, 1968, 1969).

The specifically human sciences include psychology, anthropology, sociology, history, economics, and politics and the studies of literature, poetry, music, fine art, and architecture. For Dilthey, sociohistorical humanity is their subject and object. Before man investigates his free and creative spirit, he finds in himself and in his society a sovereignty of the will, a responsibility for actions, the ability to know, and the struggle against every encroachment on freedom. In this realm lies every value and purpose in life, and the lived or 'lived through' experiences (*Erlebnissen*) making it up form interconnected and integral wholes or nexuses. The human sciences describe, narrate, and judge the manifold facets of sociohistorical experience, having as their concern the social and cultural systems developed to protect us from wild nature and aggression and to make our lives intelligible. All these sciences involve judgments and statements that are normatively correct or incorrect and not just logically true or false (hence in politics an institution is judged to be good to the extent that it fulfills its aims of reconciling individual freedom with civic spirit). In the lives of individuals, who are peculiar and once off intersections of social and cultural systems, we find not so much a multiplicity of causes operating blindly as a play of representations, feelings, and motives. The profusion of such interactions is boundless and value laden, so we should not subject them to methods modeled on the natural sciences, as in positivist sociology.

By contrast with the procedure of explanation, the human sciences seek to understand. In ordinary life, we understand before ever we know explicitly and communicably. Everyday understanding articulates lived experience, tacitly comprehending the relationships of parts to wholes and vice versa, whether of things or other people or psychic states. In what Martin Heidegger (1889–1976) was to entitle the 'hermeneutic circle' of developing understanding, we move from wholes to parts and back again, a conception itself inherited from Schleiermacher. On this basis, Dilthey contends that the human sciences can interpret life, with interpretation denoting systematic understanding. Because man as a fact prior to history and society is a fiction, we must begin to interpret ourselves through the allied disciplines of psychology and anthropology, explicating the inner conscious world of the individual – whether of the artist or the person of action – together with his or her milieu. From here we progress to history and the other human studies. Dilthey stresses, however, that the procedures and results of the natural and human sciences are not hermetically sealed. As psychophysical beings we depend on natural processes, as witnessed by our biology and sensory apparatus and by the importance of understanding laws of sound formation as well as of meaning in linguistics and music. Conversely, our purposes and actions have their repercussions on nature and the earth, which we have made into our home and dominate increasingly. Thus we can see how relative the delimitation of these sciences actually is.

Understanding can never be purely cognitive or disinterested, claims Dilthey, since knowing is internally related to feeling and willing, all three constituting the nexus of each lived experience. Knowing includes perceiving, imagining, remembering, and other forms of representing and symbolizing, and with Kant employs conceptual categories in developed human awareness. Feeling involves pleasure and pain, and pertains primarily to one's own affective state or to a situation embracing others or the world of which the state is a part. In simpler feelings neither the state of the subject nor the objectivity of the object is clearly distinguishable. Such feelings can be pains like toothaches or indeed moods without any objects. In concert with the will, feeling gives historically emergent conceptual categories their purchase on external reality. If children had not felt their actions and passions in and through their bodies, for instance, the concept of causality could never gain a living significance. Against Kantian formalism, conceptual categories must be preceded genetically by categories of life having their own experiential form and content. With higher feelings such as those evoked by music or by the selfless actions of others, a feeling and its object can be better separated. Yet feeling is always some mode of empathically apprehending other people and properties of nature that knowledge cannot fathom fully.

Willing covers biological impulses, precognitive striving, and volitional activity. At its primitive level it is present through the entire body, and therefore places outside itself what is encountered in touch. Due to the fact that external reality influences us, resists the will, and is present in feelings of pleasure and pain, it is given to us as reality rather than as bare phenomenon. Through the impulse of will and the resistance to will, maintains Dilthey, we acquire within the nexus of our representations a reflexive awareness of ourselves as distinct from others. This is at first an inchoate awareness of being there as subjects of experience, not yet of what we are. Willing in its volitional forms is related to situations that ought to be realized, and is accompanied by representations of objectives and of the means to realize them. Only a minority of our choices can be realized proximately or at all, so our lives are permeated by a struggle between representations and realities. In the earlier drafts for the second part of the Critique, the complexity of a lived experience is further elucidated by a focus on its temporality. The present is a living state shown in attention, feeling, and willing, and even in abstraction from its contents is distinct from the past and the future.

The unity of knowing, feeling, and willing is writ large in the sociohistorical reality studied by history, sociology, economics, and politics and enlivened by the arts. We are born into external organizations of society, instituted nexuses such as the family and the state with their preexisting relationships of property and dependency. The power structures of the state have their genesis in the commanding and obeying that we first encounter in the family circle, and must also appeal to feeling and reason to survive. The known and felt justification of these structures, furthermore, is essential to healthy progress. In growing up we expand into cultural systems, which are voluntary associations that we join to further our purposes through cooperation and to enhance our sense of the value and ultimate significance of life. Though the isolated individual is a fiction, contends Dilthey, each individual contributes to and

thus modifies the social systems that intersect in him or her. Impersonal and ahistorical systems are no less abstractions than atomic and ahistorical human beings, though we must avoid mystical notions such as a 'national culture' or 'spirit of a people,' which apart from their pernicious possibilities are unusable for understanding and explanation. The individual must contrast with generality to be recognized, but is ineffable. Following Schleiermacher, every individual, in principle, exceeds his or her comprehension. Dilthey maintains that the human sciences are irreducible to each other, whatever their commonality and order of precedence may be. The repeated references to sociohistorical reality reflect his claim that no discipline can collapse human life into the categories of interpretation peculiar to it.

The middle period of Dilthey's career is marked by *The Origin of Our Belief in the Reality of the External World and Its Justification* and *Ideas for a Descriptive and Analytic Psychology*. In the first work, he explicates in greater detail the contributions of feeling and willing to our sense of the world as reality rather than mere appearance. In the other, he invests much confidence in the strength of psychological method, already conceived in his earlier work as the starting point for the human sciences. To account for human and sociohistorical reality, we must eschew explanatory psychology and proceed in a purely descriptive manner. Modeled on the methodology of the natural sciences, the explanatory approach places far too much reliance on hypotheses of physiological causality and empirical association. It fails to appreciate that we already encounter interconnected wholes in early experience, and has little to say about the immanent evolution of character and perspective through the course of life, which is not of necessity a development for the better in this or that person. The fecundity of description has been well illustrated in great novels, poems, biographies, and autobiographies, which portray the higher forms of human experience, the intrinsic shape and value of individual character in different stages of life, and the variety of creative geniuses who have developed and continue to develop our sociohistorical world in its moral and aesthetic richness. A properly descriptive psychology will systematize these forms of description, allowing us to move rigorously from the outer to the inner, that is, to our inner psychic states in their underlying structural unities and in their individual singularities.

Dilthey's descriptive and structural psychology was criticized heavily by Wilhelm Windelband (1848–1915), Heinrich Rickert (1863–1936), and his former student Hermann Ebbinghaus (1850–1909). For Ebbinghaus, the descriptive methodology ignores the difficult experimental work and demonstrable findings of explanatory psychology. This problem apart, it is assumed that description can be carried out without making use of hidden hypotheses and sliding into inferences. Against the initial criticism, Dilthey's psychology was not confined to description, also being framed to work from common and intersubjectively verifiable (if not ahistorical) features of lived experience back to their structural conditions in a broadly Kantian fashion. Yet he came to concur that hypotheses and inferences were impossible to avoid. There has recently been a shift in the view of the impact of these criticisms and the scope of the novel approach taken by Dilthey in the final phase of his career. The earlier view is that the criticisms motivated him to reject the psychological approach and to formulate a thoroughgoing alternative (Bollnow, 1936). Newer scholarship suggests that he downplayed descriptive psychology without abandoning it, maintaining that it had a valid but limited range. On this reading his second methodology complemented it, and was motivated by a deepening appreciation of the temporality and historicity of life and lived experience predating these criticisms (Grondin, 1994; De Mul, 2004). Certainly he no longer regards psychology as the single foundation of the human sciences, and comes to voice objections to reflective and introspective procedures signaling the need for a further approach.

Hermeneutics, Expressions of Life, and Worldviews

Dilthey's last phase was heralded in the programmatic sections of 'The Rise of Hermeneutics.' The most detailed works of this period are *The Formation of the Historical World in the Human Sciences* and the posthumous *Drafts for a Critique of Historical Reason*. A lived experience of knowing, feeling, and willing is now construed as a unitary episode of meaning having an internal relationship to the past and future, such that the former is still efficacious and the latter already efficacious within it. The past is never restricted to what has lapsed, for it is understood as continuing to color and orient us in its being settled. We only rage against it in knowing the futility of our dreams as to how it could have been different. In our understanding of the future, we take ourselves as free and active. We grasp that we have manifold possibilities (at least prior to old age), yet our explicitly facing forward presupposes a projective attitude in which the future has some definite shape toward which we plan as well as strive. The present is the moment of living and suffering and willing and acting in the streaming nexus. Within the flow of presently lived experience all of our bonds to what we remember and anticipate pull us along backward and forward, constantly and ineliminably. Temporality is the first category of life, and fundamental for all the others.

The temporality of life in the extended sense is its overall course. Though its meaning can be reconstructed as a whole through recollection, it is limited by birth and death, and most especially by death. Our relationship to the event ending life is crucial to life's understanding and evaluation. Psychological reflection as introspection is inadequate to these longer and shorter nexuses of lived experience. Try as we might to focus on the flow of experience itself, we are subject to the law of life in which every observed moment of life is remembered and thus extracted from its flow. It is fixed by attention, as Dilthey puts it, which arrests what is essentially fluid. Nor can attention grasp the reaching beyond itself of each lived experience, since in ordinary awareness there is no separation of subject and object. Only within thinking is the experience and what is experienced is objectified. Evident is a proximity to Friedrich Nietzsche (1844–1900), with whose ideas Dilthey was familiar. As for the course of life, it emerges from millennia of sociohistorical as well as biological development. Each individual we encounter is an intersection of sociohistorical structures, who has and will actualize some of the possibilities opened up by these structures, but not others. Herein lies the individual's

historicity, though he or she is only given by way of realized possibilities. The knowledge we endeavor to gain reflectively is in any event slanted by the language we must use and the questions that we pose. Life is finally an enigma that we cannot solve or explain in an equation. Behind it our thinking cannot go; it is unable to fathom the life from which it has emerged. What is discoverable about humanity, only history can tell us.

Such is the backdrop to Dilthey's later method for interpreting or systematically understanding individual and socio-historical 'expressions of life.' It comprises the study of observable utterances and actions and larger and more enduring creations, from states, legal codes, and religions through to our no less important works of art and architecture. Again we move from the outer to the inner, this time understanding our own lives and those of others by way of expressions. The aspect of inner life to which we return with this approach, however, is not that of psychic acts. It is composed instead of the meanings, contents, or spiritual significances of these acts, through which we refer to objects. Dilthey is here influenced by Edmund Husserl (1859–1938), who refined the schema of act, content, and object in his investigations of the intentionality or directedness of awareness. Through the study of expressions, maintains Dilthey, we can apprehend the meaning of the attitudes that we commonly assume in life – projecting, valuing, disapproving, and the like – and those of other cultures and epochs. We can also apprehend the way in which creative individuals combine and rework inherited nexuses of significance. Examining individual expressions systematically enables us attain results possessing universal validity, showing the inner structure and lawfulness of instituted forms and meanings. Drama, for instance, is a peculiar nexus of material, poetic mood, motif, plot, and means of presentation.

Every expression is an objectification of life. Once molded and cast into the world, it is publicly available and relatively permanent. Dilthey thus widens the range of spiritual significance rendered concrete that Hegel called objective spirit (Hodges, 1952). The field of interpretation embraces paintings, statues, buildings, and monuments that are mute and silent (unlike novels, poems, musical scores, and speeches) and therefore dependent on dedicated literature for their explication. Interpretation culminates in the elucidation of the written records of human existence. As an art it is the basis of philology, and the science of this art is hermeneutics. The art of hermeneutics can be systematized and lead to objective and universal validities because we can return to solid and graphically inscribed expressions over and again, checking and deepening our understandings of their meaning and isolating those procedures recursively useful in earlier interpretations. This is how we reach general maxims and rules of interpretation. The latter cannot serve as substitutes for interpreters of genius, but do shorten the way for their successors. Interpretation could not begin if expressions of life were utterly unfamiliar, but would be superfluous if there were nothing strange in them to arouse our interest. Hence the expanding hermeneutical circle in which the interpreter goes from a whole to its parts and back again operates between the strange and the familiar.

Dilthey argues that expressions of life can be divided into three major classes: those of logic, of action, and of lived experiences. Logical expressions are made up of concepts and judgments and the systems and theories built out of them. Pertaining to scientific and practical works, they have meaning contents expressing and conforming to logical laws, and therefore remaining identical in various contexts and indifferent to them. Precisely as logical they can be understood technically or completely, but convey nothing of the individual meaning nexuses in the lives from which they arose. Expressions of action comprise observable movements directed toward planned outcomes. The whole tapestry of human actions is initially woven out of basic operations like the lifting of a door latch, the swinging of a hammer, or the sawing of wood, which immediately manifest the presence of certain purposes. These expressions do not carry particular references to the meaning nexuses of individual lives, and do not spring primarily from an intention to communicate to contemporaries and descendents. We understand all such expressions practically.

The third and most important class is that of expressions of lived experiences. They include facial and bodily gestures, speeches, ceremonies, and rituals and the entire field of literature, art, music, and architecture. They usually originate with intentions to communicate that go beyond practicalities, but may also have arisen with no intent to express spirit, though they nevertheless make it understandable. Some of them bring us into the realm of the highest aesthetic, moral, and religious values, where instrumental purposes fall away almost completely. In the higher understanding of such expressions, what is significant is not their truth or falsity but their truthfulness or untruthfulness, in the sense of what they make manifest or what they occlude. A great work of art can open up the whole world of individual and communal meaning within which it was created. Some of these enduring creations reveal nexuses of meaning that were not consciously present to their creators and their fellows, and that were passed over by earlier interpreters, since they embody and appeal to historically mediated feeling and will, not merely giving rise to knowledge. Thus an expression of lived experience may contain more significance than any process of introspection could ever catch sight of. It taps into and draws from levels not illuminated by consciousness, which rises like a small island out of these inaccessible depths. This is why the meaning intended by its author or creator may not be the key to the truthfulness of an expression.

Higher understanding would be impossible if its way was not prepared by its elementary predecessor. The child grows up within the order and ethos of the family that it shares with its other members, and is wholly immersed in commonalities. Before it learns to speak, remarks Dilthey, it has understood gestures, facial expressions, movements, and exclamations. It repeatedly encounters them as the same and in the same relation to what they mean and express. In earliest childhood, we also encounter squares planted with trees and rooms with peculiar arrangements of chairs. These become understood because human planning, ordering, and valuing have assigned a place to every square and to every object in a room. Thus the individual becomes oriented in the world of objective spirit, and with the acquisition of language learns to consciously articulate the world into wholes and parts and I and you and they. The higher forms of understanding are aimed at in the

elementary forms. Lived experiences gradually become more nuanced, and understanding is raised again in linguistic expressivity, which does not just report higher nexuses of meaning, but produces them. As our horizons widen in the triadic progression from lived experience to understanding the expression, the path is opened from the common to the universal.

Hermeneutic interpretation has the near aim of systematizing higher understanding. With its rules or maxims of interpretation, we can more easily transpose ourselves into the life of another, recreating and reexperiencing the nexus of individual and sociohistorial meaning involved in his or her expressions. This approach is not empathic, though it serves to underpin refined empathy and sympathy. Religious experiences are alien to secularized Europeans, for example, but on reading Luther and his contemporaries, we can transpose ourselves into his world, learning how his spiritual consciousness was fostered in a monastery and by studying St Augustine, how church councils and religious orders had spread the idea of an invisible church, and how Christianity as a force for shaping life was converging with the spirit of the age in the cities and in the artworks of Sachs and Dürer. In this manner the effectiveness of history on ourselves is widened and deepened, and we are emancipated by historical understanding. We can now grasp the final aim of hermeneutics, that of lifting us above the limitations of our time and place, freeing us and fostering an informed appreciation of human values in and of other epochs and cultures. Entering into another context is liberating for the individual interpreter or later reader because comparative understanding is gained, allowing his or her own life context to be clarified and enriched.

In his last years, Dilthey formulated a philosophy of worldviews that supplemented his hermeneutics of individual and sociohistorical expression. Evolutionary theory and the knowledge of the relativity and transience of every historical form of life, religion, and metaphysical system have undercut the claim of any philosophy to express the order of natural and human reality. From the outset, Dilthey had regarded metaphysics as unscientific, the 'queen of a shadow realm,' and he now devotes attention to what Nietzsche had regarded as the metaphysical need of human beings to posit something fixed and permanent beyond change. This leads them to develop worldviews or overarching pictures of the cosmos, each of which offers a comprehensive plan of life, an ideal model of personal and societal life, elevated norms of conduct, and a highest good. Like the external organizations and cultural systems informed by it, a worldview must appeal to knowledge, feeling, and will to take root and thrive, even if its extrapolations beyond lived experience lack scientific validity. As with life itself, a worldview goes through the stages of youth, middle, and old age, though it will not disappear completely if it speaks to our more enduring dreams and wishes.

Religious worldviews originate in experiences of an unseen reality only convincing to those who have had them personally, or whose testimony is persuasive to those open to the idea of such a reality. These experiences are gradually solidified into dogmas and then into more argued justifications that cannot substitute for the first hand experiences. It is the fate of every religious worldview to lose its original inspiration and to become entangled in irresolvable contradictions. Artistic worldviews have been nourished historically by religion, but have more recently attained a measure of autonomy. They appeal vividly to feeling and willing in their symbolization of general nexuses of meaning, and artists and poets typically embody the widest variety of creative capacities. The artistic genius is usually a free and healthy person who develops the affective life of humanity. The understanding of life as an aesthetic phenomenon is for all that unsystematic, and philosophical worldviews seek both systematicity and universality. Despite the anarchy of competing schemes, we can distinguish philosophical worldviews that are scientific and naturalistic, subjectively idealistic, and objectively idealistic. The first appeals primarily if not exclusively to theoretical and instrumental cognition, the second to the will and the evaluation of life, and the third to needs and purposes, appealing above all to feeling. But in the end, there is no teleology of history in which one worldview must thoroughly supplant another, and no one will fathom the mysteries of life or death or the course of living, in which all things flow and change.

Criticisms and Influence

Dilthey's notions of understanding, interpretation, nexus, lived experience, and worldview have all filtered into antipositivist and interpretative sociology. He has been taken as a classical sociological theorist (Bakker, 1999) and a core source of qualitative, ethnographic symbolic interactionism, and phenomenological sociology (Prus, 1996). His main influence has been in European philosophy, where many of critics have drawn extensively on his work. Husserl accuses him of epistemological and historical relativism, though he never questioned the validity of logical truths, and it has been contended that his historical relativism is carefully qualified. He implicitly differentiates statements within historically bound structures from meta-statements about them. Between as well as within epochs and cultures, temporality is intrinsic to life, human creativity asserts itself continuously, and historical consciousness frees us from one-sided views of human reality. It is conceded, however, that the universal validity of such meta-statements is only claimed, and that these statements are revisable, however warranted to date (De Mul, 2004). Husserl himself shows the marked influence of Dilthey in his emphasis on description and in his genetic phenomenologies of preconceptual sense, of the life world (Makkreel, 1982), of inscription in the growth of modern science, and of homeworlds and the problem of understanding alienworlds.

In the view of Heidegger, the very terminology of life retains essentialist and biologist connotations that obscure our free, self-transformable existence as possibility. He goes on to claim that Dilthey's stress on the knowledge of history is at the expense of our projective historicity (Bambach, 1995). The majority of ideas in his thought are nonetheless deeply indebted to Dilthey, from historicity, understanding, and interpretation to temporality, 'Being-towards-death,' and the world-disclosing powers of art and poetry. A no less critical, and for many years dominant, reading is that of Hans-Georg Gadamer (1900–2002), who sees an unresolved tension in Dilthey's writings between historical relativism and scientism. On this interpretation, relativism is so much not

the problem as a continued commitment to the natural scientific ideal of attaining universal and atemporal validities, evidenced further by the positivistic conceptions of objectivity sometimes employed by Dilthey and by his view of hermeneutics as a methodological foundation for the other human sciences. He is also taken to privilege present-day perspectives, construing the past as a text whose understanding may clarify and enrich but not overthrow them, though each 'fusion of horizons' in which the present is genuinely confronted by the past ensues in a higher understanding that overcomes both perspectives without ever ending the hermeneutic task (Gadamer, 1960). Yet Gadamer leans heavily on Dilthey's idea of effective history, and it is arguable that the latter would have little difficulty accommodating such fusions. As for the other accusations, Dilthey never gives hermeneutics the role once assigned to psychology, and retains a fallibilist view of objectivity irreconcilable with positivism. But it is fair to hold that he does not clarify the relations of his approaches to each other (Weiss, 1991; Grondin, 1994).

Dilthey's ideas have also been adapted by Emilio Betti (1890–1968), Karl-Otto Apel (1922 to present), Jürgen Habermas (1929 to present), and Eric Hirsch (1928 to present). All posit conditions of objective understanding and interpretation seek to purify hermeneutics of relativism. Though not himself a relativist, Paul Ricoeur (1913–2005) is a methodological pluralist who finds an inevitable conflict of interpretations of human existence, with no paradigm properly accounting for its rivals, as prefigured by Dilthey's insistence on the relative autonomy of each human science and primary appeal of each worldview. In Ricoeur's subsequent theory of narrative identity, one's sense of being an enduring self and dependable moral agent through significant life changes is itself constituted by the revisable story that one tells about oneself with the help of others. The theory endeavors to account for the nexus or connectedness of life we ordinarily affirm of ourselves, and reflects Dilthey's interests in reconstruction from memory and autobiography. Dilthey has influenced American analytic philosophy by way of Heidegger and Gadamer, notably in the thought of Richard Rorty (1931–2007) and Donald Davidson (1917–2003). Rorty espouses an epistemological and ontological relativism and describes philosophy as akin to poetry, whereas Davidson regards effective history and the fusion of horizons as filling out his theory of radical interpretation, which opposes what he identifies as the empiricist and relativist dogma of conceptual schemes that are in principle untranslatable. The fact that Dilthey's influence has generally been through his successors is largely responsible for his comparative lack of prominence as a philosopher, and it is only in the last few decades that his reputation has grown in the English-speaking world.

Dimensional Comparisons and Their Consequences for Self-Concept, Motivation, and Emotion

Jens Möller, Friederike Helm, Hanno Müller-Kalthoff, and Nicole Nagy, University of Kiel, Kiel, Germany

Abstract

A comparison process that is distinct from but related to social and temporal comparisons is introduced – dimensional comparison. Using an internal frame of reference, dimensional comparison entails a single individual or group comparing his or her ability in a target domain with his or her ability in a standard domain (e.g., "How good am I in math compared to English?"). Dimensional comparisons usually reduce self-concept in the worse-off domain and increase self-concept in the better-off domain. This article presents the basic principles of dimensional comparison in 10 hypotheses, covering their antecedents and their consequences for self-concept, motivation, and emotion, as indicated by introspective, path-analytic, and experimental studies.

Each evaluation of a certain target is based on a comparison with a certain standard (Kahneman and Miller, 1986). Two of the most prominent comparison processes used to explain self-evaluations are social and temporal comparisons. Social comparisons use information on others as the standard (Festinger, 1954) while temporal comparisons use prior information on oneself as the standard (Albert, 1977). A third kind of comparison process, becoming more and more important in educational research (see Eccles, 2009), is dimensional comparison. Dimensional comparisons are intraindividual comparisons that use information from one or more comparison standards within oneself when evaluating a certain target. The term *dimensional comparison*, first used by Möller and Köller (2001a), closely references what Marsh (1986), in relation to his Internal/External frame of reference model (I/E model; see the chapter by Marsh et al., in this volume) has described as the result of an internal frame of reference. Namely, the negative impact of achievement in one domain on self-concept in another domain: A student performing better in a verbal than in a math domain tends to have a lower self-perception of his or her math ability than does a student with identical math ability but lower verbal ability.

Going beyond the I/E model, the dimensional comparison theory (DCT; Möller and Marsh, 2013) points to the psychological processes behind this so-called contrast effect. In DCT, dimensional comparisons are defined as taking place when people compare their ability in one domain (the target domain) with their ability in one or more, other domains (the standard domain/domains). The purpose of this article is to present the basic psychological principles of DCT in 10 hypotheses (see **Table 1**). Doing this, we follow Festinger's (1954) approach in formulating 10 hypotheses on social comparison theory (SCT) and Albert's (1977) similar approach in formulating 10 hypotheses on temporal comparison theory (TCT). While Albert derived these 10 hypotheses on TCT by conceptually translating Festinger's 10 hypotheses on SCT to the context of temporal comparisons, a simple transformation of SCT or TCT hypotheses to a dimensional comparison context was deemed inadequate: Some of these hypotheses do not fit DCT, while others have been falsified by subsequent research. However, the idea of developing hypotheses as a basis for DCT does seem profitable to us.

Table 1 Ten hypotheses on dimensional comparisons

I	People carry out dimensional comparisons that are intraindividual comparisons of their own abilities in different domains.
II	People prefer domains as comparison standards that share relative attributes with the target domain.
III	Most dimensional comparisons are upward comparisons with a better-off domain.
IV	Dimensional comparisons serve motivational needs (for self-differentiation, self-enhancement, self-evaluation, self-improvement, and self-maintenance).
V	Dimensional comparisons are triggered by external forces.
VI	Dimensional comparisons lead to contrast effects in self-evaluations (when the respective abilities are believed to be negatively correlated).
VII	Dimensional comparisons lead to assimilation effects in self-evaluations (when the respective abilities are believed to be positively correlated).
VIII	The net effect of dimensional comparisons is positive.
IX	Dimensional comparisons also influence mood and behavior.
X	Dimensional comparisons influence evaluations of and by other people and groups.

In our view, DCT should extend research on the I/E model to detect the psychological processes behind it. In doing so, it should deliver testable hypotheses to enrich future research on the psychological process of dimensional comparison, its antecedents and effects, in educational and other fields. Whereas research on dimensional comparison is well-known in self-concept research in educational psychology (and in sport psychology; see Chanal et al., 2009; Tietjens et al., 2005) it is largely ignored in other related fields, such as social psychology or organizational psychology. It is a central purpose of this article to serve as a bridge to other disciplines of psychology, where the theoretical conclusions as well as the empirical support presented in this article should prove useful for further research as well.

Therefore, we explore each of the hypotheses presented in **Table 1** individually, outlining the assumptions related to each hypothesis, followed by discussion of relevant research results and examining theoretical support.

Dimensional Comparisons in 10 Hypotheses

Hypothesis I

People carry out dimensional comparisons that are intraindividual comparisons of their own abilities in different domains.

Hypothesis I postulates that people compare their ability in a target domain with their ability in a standard domain (e.g., "How good am I in English compared to math?," where English is the target domain and math the standard domain). Dimensional comparison processes do impact on self-evaluations of ability, as many field studies on the I/E model in educational psychology have shown (see Goal-Oriented Behavior Among Human and Non-Human Primates). Yet, within those field studies it is often impossible to differentiate between a certain target and a certain standard domain. In most studies, students were asked for their self-concepts in both target and standard subjects simultaneously. Therefore, the negative contrast effects from math achievement on verbal self-concept and from verbal achievement on math self-concept were only interpreted post hoc as dimensional comparisons. In contrast, it is much easier to use the terminology of standard and target domains in experimental studies with a carefully designed causal-temporal course of events or in introspective studies, where participants can be asked which domain served as a target and which domain served as a standard (cf Möller and Marsh, 2013).

In one such introspective study, Möller and Husemann (2006) asked students to report spontaneously emerging dimensional comparisons in their everyday lives. Participants were told to note and describe any dimensional comparisons that came to their mind during a period of 14 days. In two studies, university students and high school students recorded an average of more than six dimensional comparisons during the 14-day period. In addition, students were asked to mark which domain served as target and which domain served as the comparison standard. Results showed that academic matters were most commonly used as target domains as well as standard domains (i.e., "We were given our school reports and I compared my grade in religion with my grade in mathematics"). Personal relationships and characteristics were also used, yet less frequently ("Although I am not that thin, I am not touchy").

Another introspective study (Möller and Weber, 2001) asked a sample of $N = 105$ adults between 65 and 92 years of age to make self-evaluations on mental flexibility and memory, physical fitness and health, and ability to cope with problems. Participants were asked to conduct dimensional comparisons of their ability in each of the three domains with their general ability level. Participants considered these dimensional comparisons to be more important than, and often preferred them to, social comparisons or temporal comparisons. Dimensional comparisons also seemed to result in more positive self-evaluations than did temporal or social comparisons, for this particular sample.

In their experimental studies, Möller and Köller (2001a) found direct evidence for the occurrence and for the effects of dimensional comparisons. In one study, participants were given randomly assigned achievement feedback on a math task (above average vs below average) and were asked to complete scales assessing their perceived mathematical and verbal competencies. Even without any direct reference to their achievement in the verbal domain, positive feedback on math achievement led to a lower verbal self-concept; negative feedback on math achievement led to a higher verbal self-concept. The authors concluded that it is sufficient to give achievement feedback for one domain only – in support of Hypothesis I; it is the individual who deduces differences in his or her own ability between two domains while carrying out dimensional comparisons.

Hypothesis II

People prefer domains as comparison standards that share relative attributes with the target domain.

Hypothesis II suggests a standard selection process, a more or less free and intentional choice of comparison standard. Following Goethals and Darley (1977), similarity on related attributes drives the standard selection process within social comparison processes. Within dimensional comparison processes, people who self-evaluate a particular target domain can choose between a variety of other domains that could potentially serve as the comparison standard. Research on the I/E model does not deal with the antecedents of dimensional comparisons, since students are normally asked for their self-concepts in two domains. Thus, conclusions as to how they carry out dimensional comparisons between their abilities in these domains are post hoc only (see Möller and Marsh, 2013). However, in the experimental design of Möller and Köller (2001a), it was shown that students also spontaneously choose the verbal domain as a comparison standard when they receive math feedback. Furthermore, the majority of the spontaneous dimensional comparisons reported in the diary studies by Möller and Husemann (2006) were indeed between domains that belonged to the same context, e.g., an academic or a social context, and therefore shared particular attributes. For example, one participant compared her relation to her parents: "Last time it still didn't work out with my father, but I got along better with my girlfriend." Such context or content similarity may elicit the choice of standard. In Möller and Husemann (2006), dimensional comparisons within the academic field (e.g., between similar aspects of academic life) represented the most frequently used single target–standard combination, at 15% of all comparisons. In accord with Hypothesis II, the comparisons shared similar metrics as a relative attribute; for example, math and verbal ability share common metrics such as grades or test scores.

Hypothesis III

Most dimensional comparisons are upward comparisons with a better-off standard domain.

Hypothesis III of DCT is in correspondence with SCT's hypothesis that "there is an unidirectional drive upward in the case of abilities" (cf Festinger, 1954, p. 124). Upward comparisons may be triggered by self-improvement motivation, and

the aspiration to derive hints from analyzing the results of better-off domains. A student, comparing his worse math grade with his better English grade, may perform an upward dimensional comparison from the perspective of his math ability. When people are free to choose the dimensional comparison direction, most of them compare (slightly) upward, as our diary studies showed (Möller and Husemann, 2006). Most dimensional comparisons in both studies were rated upward by the participants: In the majority of dimensional comparisons the comparison standard was rated as slightly better than the target. Therefore, Festinger's Hypothesis IV from SCT is directly transferrable to DCT.

This is of particular interest, since upward dimensional comparisons have negative outcomes for the target domain. As was demonstrated in experimental research by Möller and Köller (2001a), participants who receive frustrating achievement feedback in a task A, and additional, upward comparison ("You have achieved better in B than in A") decrease their self-concept in the intraindividually weaker target domain A, compared with a group who get identical achievement feedback in task A without the additional dimensional comparison information.

To conclude, there is very little research on spontaneous dimensional comparisons that analyses comparison direction, which Hypothesis III calls for. What we do know however is that negative mood states enhance the probability of upward comparisons, whereas positive mood triggers downward comparisons (Möller and Husemann, 2006).

Hypothesis IV

Dimensional comparisons serve motivational needs (for self-differentiation, self-enhancement, self-evaluation, self-improvement, and self-maintenance).

As described above, people carry out dimensional comparisons spontaneously, and therefore might be seen as motivated to do so. Hypothesis IV assumes that people are motivated to dimensionally compare a certain target with a certain standard, and lists prominent motivations. Although these are discussed in the literature on the self (Elliott and Dweck, 2005), there is not much empirical research on these motivations as elicitors of dimensional comparisons. Thus, the assumptions of Hypothesis IV are rather hypothetical, and should be investigated further in empirical studies of comparison motivation.

A motive for self-differentiation might trigger dimensional comparisons. Such a motive should be defined as the wish to possess a multifaceted self-concept (Marsh et al., 1988), with a complex structure integrating strengths as well as weaknesses, preferences as well as dislikes. Marsh (1986) argued that the idiosyncratic and multifaceted structure of self-concept derives both from the use of external frames of reference (in social comparisons) and internal frames of reference (dimensional comparisons). The motive for self-differentiation is strongly related to what Linville (1987) called self-complexity. She defined self-complexity as the number of distinct self-aspects a person believes himself or herself to possess. High self-complexity enables a person to buffer self-concept against stress-related events. Engaging in dimensional comparisons could be a means to trigger more complex self-views with profiled self-perceptions: comparisons between one's own abilities in different aspects of life lead to the perception of accentuated weaknesses and strengths, to highly faceted self-concepts with many distinct cognitive self-aspects. Self-evaluation motivation might also trigger dimensional comparisons. People want to know who they are, how they are doing; they want to evaluate their strengths and weaknesses. They can use dimensional comparison processes when they have to choose courses in school, to decide which degree to take at university, which job to apply for, or which hobby to take up (Dickhäuser et al., 2005; Nagy et al., 2006). However, dimensional comparisons are not always useful to evaluate domain-specific abilities correctly: Although contrast effects of dimensional comparisons may be useful in helping to detect the idiosyncratic aspects of one's own self, they are somewhat misleading as they often lead to an over- or underestimation of own abilities.

Self-enhancement and self-maintenance motivations may also trigger dimensional comparisons. When a student's self-worth is threatened by negative feedback for a target domain, their attention may switch to certain standard domains offering an escape from negative outcomes and the opportunity for compensatory self-enhancement (Baumeister, 1982). Furthermore, self-enhancement or self-maintenance needs dimensional upward comparisons: Following failure feedback, people tend to focus on strengths, not on weaknesses (cf Boney-McCoy et al., 1999; Dodgson and Wood, 1998). As Möller and Marsh (2013) point out, DCT goes beyond compensatory self-enhancement. Beside the consequences for self-worth, they conclude that dimensional comparison processes affect all involved self-evaluations negatively for the threatened (worse-off) target domain, positively for the unthreatened (better-off) standard domain.

Self-improvement motivations may also trigger upward dimensional comparisons. It can be very helpful to switch attention from a suffering target domain to one's own particular strengths as a comparison standard, when trying to improve in an area of weakness (although it leads to costs in self-concept in the target domain). Self-improvement motivation will usually trigger the choice of standard from a similar context to the target, since behavioral strategies may be more easily transferable from one domain to another when both belong to the same context.

As noted above, there is a lack of empirical studies on the motivational antecedents of dimensional comparisons. Most of the corresponding research deals with the I/E model, and just confronts students with math and verbal self-concept questionnaires, without motivational implications being addressed.

Hypothesis V

Dimensional comparisons are triggered by external forces.

Dimensional comparisons can also be seen from a nonmotivational perspective. People are not always completely free to compare dimensionally; some situations trigger dimensional comparisons more than others. Many such situations deal with strengths or weaknesses, with preferences or dislikes. Examples of external forces leading to dimensional

comparisons may include situational demand characteristics, such as when we have to choose which foreign language to take in school, whether we should specialize in arts or sciences, whether we want to become a policeman or a lawyer (Nagy et al., 2006). There is not only thrust to intraindividually compare one's own abilities in particular domains, there is also thrust to choose particular domains as standards since standard selection is not completely free (Biernat and Eidelman, 2007). Often, standard selection is directed by relative attributes that the target shares with the standard domain, as described in Hypothesis II.

Diener and Fujita (1997) have distinguished between free and forced choice approaches to social comparison. In the forced choice condition, individuals find that "comparisons are imposed or compelled" (p. 330) by environmental factors. The authors propose that in schools, students are imposed on to carry out social comparisons to evaluate their performance. To some degree, in the typical research design used in the I/E model literature, the comparison may also be seen as being 'forced': The researcher decides what subjects and what self-concepts to evaluate (e.g., math and verbal). Möller and Marsh (2013) state that in-school standards may be directly evoked by the environment. The choice of math as a standard domain following achievement feedback in English may also be prompted by accessibility and efficiency standards (Mussweiler et al., 2006): Math ability comparison may be prompted more or less automatically when a student fails an English exam. To date, support for Hypothesis V only derives from the SCT literature; research with empirical evidence for the DCT context is yet to be conducted.

Hypothesis VI

Dimensional comparisons lead to contrast effects in self-evaluations (when the respective abilities are believed to be negatively correlated).

In the context of the I/E model, dimensional comparisons prompt contrast effects; they lower self-concept in the worse-off domain and raise self-concept in the better-off domain, as a meta-analysis of all I/E studies has shown (Möller et al., 2009a). In a free-choice context (cf Diener and Fujita, 1997) a student can choose a subject with a worse achievement feedback to raise his or her relative self-concept in the target domain ("I did not do as well as expected in math, but at least I did better than in English"). This results in an increased target self-concept but is still a contrast effect since self-concept in the worse-off domain is reduced. Such contrast effects from academic achievement in one domain on self-concept in the other domain are at the heart of the I/E model. The negative effects of achievement in one subject on self-concept in a non-corresponding subject were originally the reason for positing the existence of an internal frame of reference (Marsh, 1986) and of dimensional comparisons (Möller and Köller, 2001a). These contrast effects are valid across different age groups, achievement indicators, self-concept measures, and countries (cf Marsh and Hau, 2004; Möller et al., 2009a), as well as heterogeneous samples like high or low ability students (Möller et al., 2009b). Contrast effects are also stronger when people believe that two abilities are uncorrelated or even negatively correlated (as in the case of verbal and math abilities; see Möller et al., 2006a).

As longitudinal studies have shown, dimensional comparisons lead to significant contrast effects from achievement in one domain to self-concept in another domain, even when former achievements and self-concepts are controlled for (Köller et al., 1999; Marsh and Köller, 2004; Marsh et al., 2001; Marsh and Yeung, 1998; Möller and Köller, 2001b; Möller et al., 2011).

Experimental evidence comes from Möller and Köller's (2001a) studies, which found that dimensional comparison information led to contrast effects (e.g., positive feedback in a numerical task weakened verbal self-concept even when no reference was made to the verbal domain, or when achievement feedback included explicit dimensional or social comparison information about achievement in both tasks). Furthermore, Helm et al. (under review) were able to show in a field experimental study that dimensional comparisons leading to contrast effects in verbal and numerical self-concepts can be influenced: Contrast effects are stronger when students focus on differences between the verbal and the mathematical domain than when they focus on similarities.

In conclusion, contrast effects, as well as their moderating factors, have found widespread empirical support in a variety of research designs (i.e., diary studies, experiments, and (longitudinal) field studies).

Hypothesis VII

Dimensional comparisons lead to assimilation effects in self-evaluations (when the respective abilities are believed to be positively correlated).

Despite the negative effects of dimensional comparisons, as discussed in regard to Hypothesis VI, positive effects may also occur, following dimensional comparisons. While contrast effects appear when the evaluation of a target departs from the standard, assimilation effects appear when the evaluation of a target converges to the standard. Assimilation and contrast are perceived as two sides of a coin – their juxtaposition is responsible for the net outcome of comparison processes. With regard to social comparison, Wheeler and Suls (2005) claim that "probably every social comparison creates both the pull of assimilation and the push of contrast" (p. 576). Hypotheses VI and VII postulate that this statement is also valid for dimensional comparisons.

In social comparison research, upward social comparisons with higher-performing students do not always lower the self-concept as a result of contrast processes; under particular conditions they may lead to self-concept enhancement through assimilation processes (when a student concludes that he has the potential to become as good as the better-off comparison standard in the future; cf Wheeler and Suls, 2005).

With regard to dimensional comparisons, the juxtaposition of assimilation and contrast effects is particularly interesting, since assimilation processes are also conceivable in the logic of the I/E model. Sometimes, when students compare their abilities from two subjects within the one cluster (e.g., either

verbal or science), positive assimilation effects from achievement in one subject (such as math) on self-concept in another subject (e.g., physics) occur (cf Chiu, 2012; Marsh et al., 2001; Möller et al., 2006b; Nagy et al., 2006; Rost et al., 2005). As Marsh et al. (this volume) point out, results are ambiguous when both target and standard come from the same (math or verbal) cluster of the academic self-concept continuum: Some cross paths, from achievement to noncorresponding self-concept, are negative, some positive, some are near zero. Ambiguity may be caused by students' beliefs as to whether two abilities are positively correlated or not: Most students believe that math and verbal ability are negatively correlated, although in reality they are positively correlated, as empirical findings show (Möller et al., 2006a). In contrast, most students believe that math and physics achievements are positively correlated (Möller et al., 2006a; Rost et al., 2005). Different ability beliefs may predict either contrast or assimilation effects.

In our view it is possible that every comparison process leads both to assimilation and to contrast at the same time. Therefore, if assimilation and contrast effects of a similar size occur, it is possible that near zero effects will emerge as the net effect of dimensional comparisons. Further research is needed to disentangle assimilation and contrast effects in dimensional comparisons.

Hypothesis VIII

The net effect of dimensional comparisons is positive.

Even with the possibility of near zero effects in mind (see the section 'Hypothesis VII'), the net effect of dimensional comparisons can be assumed to be typically positive. For example, Möller and Pohlmann (2010) reported positive net effects for social comparisons. That is, the positive effects of downward social comparisons on self-concept were stronger in size than the negative effects of upward social comparisons. Transferring this approach to DCT, Pohlmann and Möller (2009) found in experimental and in field studies that positive self-concept effects for downward dimensional comparisons were larger than negative effects for upward dimensional comparisons. Positive net effects were shown both in self-perceived competence and in satisfaction with test outcomes. These findings are congruent with the findings of Möller and Köller's (2001a) experimental studies.

The overall benefit in the use of dimensional comparisons suggests that people use dimensional comparisons as a way of regulating their self-evaluations in a self-enhancing way (cf the section 'Hypothesis IV'; Möller and Marsh, 2013). As is discussed in more detail, in relation to the following Hypothesis IX, this finding is also valid for mood states.

Hypothesis IX

Dimensional comparisons also influence mood and behavior.

As discussed in most of these hypotheses, dimensional comparisons affect self-evaluations. Only a few studies however have investigated the effects of dimensional comparisons on variables other than self-concept. Goetz et al. (2008) examined the antecedents of academic emotions and found that math performance negatively predicted enjoyment of language arts classes, while that language arts performance negatively predicted enjoyment of math classes. Pohlmann and Möller (2009), in an experimental setting, found larger effects for downward than for upward dimensional comparisons in both self-concept and satisfaction with test outcomes. In their diary studies, Möller and Husemann (2006) found an impact of dimensional comparisons on mood states. When participants rated the comparison direction as downward (target compared with a worse-off standard), mood states became worse. When participants carried out upward dimensional comparisons (target compared with a better-off standard), mood states improved (see **Table 2**). People experiencing feelings of dissatisfaction in one domain (e.g., following bad or sad news) may initiate an upward dimensional comparison process with another domain (Schwarz and Clore, 1996), resulting in enhancement of general self-worth, as outlined above.

Looking for more behavioral consequences of dimensional comparisons, Miller (2000) found slightly negative effects of English achievement on self-regulated learning strategies in math and almost no effect of math achievement on English learning strategies. With regard to course choices, research on dimensional comparisons shows that math achievement negatively impacts on subsequent engagement, course choices, and university entry in the noncorresponding verbal subject (Dickhäuser et al., 2005; Nagy et al., 2006). Such findings support the assumption that dimensional comparisons are motivated by a kind of a self-differentiation motivation, as Hypothesis IV describes.

Hypothesis X

Dimensional comparisons influence evaluations of and by other people and groups.

When teachers, parents, or classmates are asked to infer a student's math or verbal self-concept, contrary to expectations from the I/E model (Marsh, 1986), findings do not show strong negative effects from noncorresponding achievements (Dai, 2002; Marsh et al., 1984; Pohlmann et al., 2004). Inferred

Table 2 Upward and downward dimensional comparisons and their consequences for self-concept, motivation, course choice, and mood

Target: verbal achievement	*Standard: math achievement*	*Comparison direction (seen from the target)*	*Consequence for verbal self-concept, motivation, course choice*	*Consequence for math self-concept, motivation, course choice*	*Consequence for mood*
Average	Better	Upward	Diminution	Enhancement	Better
	Worse	Downward	Enhancement	Diminution	Worse

self-concepts seem highly determined by the corresponding achievements (but see Möller (2005) for negative effects of dimensional comparisons following praise and criticism). Nevertheless, it may be premature to conclude that dimensional comparisons play no role in the evaluations of other people.

For example, Dickhäuser (2005) assumed that observers by default do not possess distinctive achievement information about their observed target and thus do not engage in dimensional comparisons; nor do they fall victim to contrast effects when inferring someone else's self-concept. In an experimental study, $N = 160$ participants were informed of a fictional student's achievement in German and math. Results showed that inferred German self-concept was higher when German achievement was high and math achievement was low.

As Möller and Marsh (2013) point out, research on group perception deals with a phenomenon that may be connected to dimensional comparisons as well: When people had to rate the warmth and the competence of groups, the group that had been presented as higher on warmth (competence) was rated as lower on the other domain, just as the DCT would predict (Yzerbyt et al., 2008).

This may be seen as one of the rare examples of research on dimensional comparison outside of purely academic realms (for another example, on the negative effect of academic achievement on honesty self-perception, see Möller and Savyon, 2003).

Conclusion

We have discussed 10 hypotheses to describe a newly developed theory of dimensional comparisons. The hypotheses define dimensional comparisons, their targets, and standards; they deal with the antecedents and effects of dimensional comparison processes. There are three central purposes for introducing the DCT. The first is to complement research on the I/E model, while focusing on dimensional comparison as the psychological process behind the interesting negative effects from achievement in one subject on self-concept in another subject. Secondly, it should deliver testable hypotheses to enrich future research on DCT. Thirdly, it should make dimensional comparison research interesting for research in other psychological subdisciplines, such as social, organizational, or cognitive psychology.

Abstract

It is important that a score based on a set of items be unidimensional – that is, there is only one latent trait underlying the items. The notion of unidimensionality can be considered in traditional test theory and item response models in terms of the relations between items, and it can also be considered in terms of the cognitive processes involved in answering items. The more recent developments of Stout and colleagues has provided important advances in methods to assess unidimensionality, and the diagnostics procedures now available can greatly improve the development of unidimensional sets of items.

A critical concern underlying the claims for validity argument relates to ensuring appropriate representation of the construct to be assessed. It is critical to ensure that the construct is neither over- nor under-represented, and that the assumption of unidimensionality is not violated (Ackerman, 1987; Luecht and Miller, 1991; Messick, 1989; Tam, 1992). This unidimensionality assumption specifies that a score can only have meaning if the set of items measures only one attribute. If the measuring instrument has a number of items that measure differing attributes it is difficult to interpret a total score from this set of items, to make psychological sense when relating variables to this total score, or to make comments about individual differences. For example, if there are 10 spelling and 10 mathematics items in a test then it is not clear what the total score for any individual could mean. For example, two students scoring 50% are not comparable as it could be that one student scored correctly on the spelling and the other scored correctly on the mathematic items. Test scores only have meaning when the items measure a single attribute (for a more complete and earlier review see Hattie, 1985).

The concept of unidimensionality is a specific instance of the principle of local independence – that is, the existence of one latent trait underlying the data. The principle of local independence requires that responses to different items are uncorrelated when θ (the person's ability) is fixed, although it does not require that items be uncorrelated over groups in which θ varies. Lord and Novick (1968) gave the definition of local independence more substantive meaning by writing that:

> an individual's performance depends on a single underlying trait if, given his value on that trait, nothing further can be learned from him that can contribute to the explanation of his performance. The proposition is that the latent trait is the only important factor and, once a person's value on the trait is determined, the behavior is random, in the sense of statistical independence (p. 538).

A set of items can be said to be unidimensional when it is possible to find a vector of values $\theta = (\theta_i)$ such that the probability of correctly answering an item k is $\pi_{ik} = f_k(\theta_i)$ and local independence holds for each value of θ. This definition is not equating unidimensionality with local independence, because it can further require that it is necessary to condition only on one θ dimension and that the probabilities p_{ik} can be expressed in terms on only one θ dimension.

McDonald (1981) outlined ways in which it is possible to weaken the strong principle of local independence. The strong principle implies that not only are the partial correlations of the test items zero when the latent traits are partialled out, but also the distinct items are then mutually statistically independent and their higher joint moments are products of their univariate moments. A weaker form is to ignore moments beyond the second order and test the dimensionality of test scores by assessing whether the residual covariances are zero (see also Lord and Novick, 1968: pp. 225, 544–554). Under the assumption of multivariate normality, the weaker form of the principle implies the strong form, as well as conversely. McDonald (1979, 1981) argued that this weakening of the principle does not create any important change in anything that can be said about the latent traits, though strictly it weakens their definition.

Stout's Evaluation of Essential Unidimensionality

Stout (1987, 1990) also used this weaker form to develop his arguments for 'essential unidimensionality.' He devised a statistical index based on the fundamental principle that local independence should hold approximately when sampling from a subpopulation of examinees of approximately equal ability. He defined essential unidimensionality as: a test $(U_1,\ldots, U_N)$ of length N is said to be essentially unidimensional if there exists a latent variable θ such that for all values of $\theta, \frac{1}{N(N-1)} \sum_{1<i\neq j<N} \left|Cov(U_i, U_j|\theta)\right| \approx 0$.

That is, on average, the conditional covariances over all item pairs must be small in magnitude (for more detail regarding the theoretical developments see Junker, 1990, 1991, 1992; Nandakumar, 1994; Nandakumar and Stout, 1993; Stout, 1990). Essential unidimensionality thus replaces local independence and is based on assessing only the dominant dimensions. Stout has developed an empirical notion of unidimensionality to match his weaker form (Stouts T-index). There are many applications of Stout's procedures (Nandakumar, 1994; Nandakumar et al., 1998), and simulation studies that have supported the value of his statistic (Hattie et al., 1996). Zhang and Stout

(1999a, b) have generalized the Stout procedure via the DETECT method (Dimensionality evaluation to enumerate contributing traits). This method simultaneously assesses the latent dimensionality structure and determines the degrees of multidimensionality present in test data. This procedure has been extended by Kim et al. (Douglas et al., 1998; Stout et al., 1996) to identify that partition P of the available k items into disjoint and exhaustive subsets that best represents the underlying dimensionality structure. The best partition is detected by $\text{DETECT}_{\max}$, and thus is a measure of the amount of departure from unidimensionality. The methods have been generalized to polytomous items (Nandakumar et al., 1998).

Thus, there are many methods for assessing unidimensionality, such as nonlinear factor analysis (NOHARM), full information item factor analysis (TESTFACT), confirmatory factor analysis via structural equations programs such as LISREL, AMOS, and testing essential dimensionality with DIMTEST, and detection of simple structure multidimensionality (DETECT).

The Concept of Unidimensionality

It is critical to note that the assumption of unidimensionality underlying most measurement models does not necessarily imply that only these models can assess the most simple of tasks. The concept of unidimensionality can be considered at various levels of analysis. At the first-order level we can construe of a set of items being combined (by appropriate weighting) to form a total unidimensional score (such as a collection of addition items leading to a total addition score). At the second-order level we can also construe of a set of first-order scores being combined to form a total undimensional score (such as a collection of addition, subtraction, multiplication, and division totals being combined to form a total arithmetic score). In both cases we can conceive of a single underlying trait.

In a different context, we could imagine a single set of items all requiring a similar cognitive process (e.g., successive or simultaneous processing) and a total score being formed – and we could consider this a unidimensional total score – even if the items were across many content domains. All too often, the notion of unidimensional has been conceived in terms of a narrowly defined set of items. The key issue is that the methods outlined to assess unidimensionality do not lead to identifying what the total score represents – this requires other validity methods (such as judgmental analyses). Identifying a unidimensional set of items is not the same as naming it.

Constructing Multidimensional Data

One of the problematic issues when assessing dimensionality is that there are differing ways that the dimensions can relate to the construct of interest. Coombs (1954) defined three methods of constructing multidimensional data: the conjunctive model, whereby an excess of one ability, no matter how large, does not compensate for lower ability in other dimensions; the disjunctive model, whereby an examinee will pass an item if he/she is dominant over the item in any one dimension and will fail only if the item dominates him/her in all dimension; and the compensatory model, whereby an examinee's response to an item is a function of a weighted sum of underlying abilities. Other researchers (notably Ackerman, 1987, 1992; Ansley and Forsyth, 1985; Reckase et al., 1986; Wang, 1987, 1988) have demonstrated that with compensatory multidimensional models the univariate calibration of two-dimensional response data can be explained in terms of the interaction between the multidimensional test information and the distribution of the two-dimensional abilities, and various interpretations of the multidimensional item difficulty, multidimensional discrimination, and multidimensional item information have been suggested.

Sympson (1978) proposed a partially compensatory model where a decrease in one ability could only be offset by a large increase in the other ability (this model has often been erroneously called a noncompensatory model). Outside of a relatively narrow ability range, the probability of passing reduces to zero regardless of the value of the stronger ability (see Lord, 1984). The probability of a correct response is simply the product of probabilities for each dimension (but see Coughlan, 1974; Jannarone, 1986).

Concluding Comments

A major need is for a clear explication of the concept of dimensionality. Within the item response literature there has been much agreement about its meaning, although it has often been (falsely) assumed that only tests consisting of 'simple' attributes could lead to a unidimensional test. Certainly there are cognitive processing models, whereby it may be possible for a student to solve an item using differing cognitive strategies, thus adding another meaning to the notion of undimensional; the unidimensionality of processes or strategies. Much of the discussion about newer models of item and test analyses is oriented around such notions (Mislevy and Gitomer, 1995).

It is critical to ensure that any set of items map the construct of interest, and if this construct is inherently multidimensional than so too should there be multiple unidimensional subtests. At this test score level, we may desire 'lumpy' items (such as reading comprehension, or mathematical problem solving), and thus the items may assess multiple dimensions while the total test still aims to assess a single 'over all' dimension. As Dorans and Lawrence (1999) have demonstrated, it is possible to conceive of situations where analysis at the test score level would reveal a single common factor, while analysis at the subscore level would uncover a few distinct subscore factors. Similarly, Reckase et al., (1988) have demonstrated that sets of items can meet the unidimensionality assumption even though they require more than one proficient for a correct response.

At present, the Stout procedures seem worth pursuing, as they are based on clear theoretical developments, are easy to use, dependably provide indications of the dimensionality, are reasonably robust, and provide a reasonably clear and practical demarcation between one and many dimensions. Further, there is need for further research on developing multidimensional models that allow for differing ways in which items or test scores can be combined, and we need better diagnostics to understand the complexity of the dimensions involved in item

and test scores. There are already many useful heuristics available to interpret multidimensional data using unidimensional calibration methods (Ackerman, 1992; Carlson, 1987; Junker, 1991, 1992; Luecht and Miller, 1991; McKinley and Reckase, 1983; Reckase et al., 1986, 1988). It is certain that discussion will continue about the concept of unidimensionality, the best forms to assess whether items are essentially unidimensional, and the importance of diagnostics to aid in constructing better unidimensional assessments.

Direct-to-Consumer Personal Genetic Testing

Sandra Soo-Jin Lee, Center for Biomedical Ethics, Stanford University Medical School, Stanford, CA, USA

© 2015 Elsevier Ltd. All rights reserved.

Abstract

As genotyping technologies have precipitously decreased in cost since the completion of the Human Genome Project, personal genetic testing has increasingly been marketed to consumers. Genetic predisposition testing is now available for an ever-expanding list of genetic mutations associated with diseases including breast cancer, Parkinson's and Alzheimer's diseases, as well as qualities such as ancestry, intelligence, and athleticism. These tests that are sold to consumers over the internet, outside of the health care system, are part of an emerging industry of direct-to-consumer (DTC) personal genetic testing. The DTC personal genetics industry provides consumers personal genetic information that interprets genotypic data into categories of relative risk and probability. Scientific and economic developments in the field of human genetics have produced a changing landscape of genetic products and services available to the public, which has fueled policy debates over questions of access, clinical and personal utility, and privacy. In addition, DTC personal genetic testing has been a focus of discourse on the potential for geneticization of social identity and questions over the meaningful extrapolation of individual genetic differences for group memberships. DTC personal genetic testing has challenged traditional approaches to genetic tests to a model of open access. The turn to the market creates new ethical, legal, and social questions as DTC personal genetic testing shifts responsibilities from the health care provider to the consumer, posing questions over who may interpret genetic information and for what purposes.

Introduction

Since the completion of the Human Genome Project, consumers have been able to purchase a broad palette of genetic tests that may range from the risk for male-patterned baldness to prostate cancer, – on the internet, without the supervision of health care providers. With relative ease, consumers can now mail cheek swabs of their DNA to commercial laboratories and within weeks receive their genetic test results online via password-protected accounts. This direct-to-consumer (DTC) model of genetic testing has garnered a significant amount of attention in the popular and scientific press over the past four years. Spearheading the shift toward what has been labeled as a democratization of health care decision making, DTC personal genetic testing companies have capitalized on technological advancements to make information more accessible to the general public by circumventing the traditional doctor–patient relationship. Unlike in Europe and other nations, DTC personal genetic testing companies, such as *23andMe, Inc.*, *Navigenics, Inc.*, and *Pathway Genomics Inc.*, have operated without significant federal regulation in the United States. However, concerns about the potential harm that DTC personal genetic products might pose to consumers have sparked policy debates regarding measures that are needed for guiding, what some have suggested resembles the 'wild west' of genomics. At the same time, some argue that regulation may threaten the nascent personal genomics industry and effectively eliminate personal genetic tests from the market. At the center of these debates are disagreements over the potential ethical, legal, and social implications of DTC genetic testing and the correct calculus for weighing individual freedom, potential harm, and the (clinical and nonmedical) utility of the information.

While it is without question that the DTC genetic testing industry requires some form of regulation to ensure both the quality and validity of the product provided to consumers, there is considerable debate over whether the current regulatory infrastructure is equipped for addressing genetic tests that are rapidly updated by genomic science. Since the boom of genome-wide association studies (GWAS) in the late 2000s – i.e., hypothesis-free 'screening' of markers across the whole genome to look for correlations with disease-related or other phenotypes – personal genetic testing offered by testing companies have focused on single nucleotide polymorphisms, or SNPs, that are single base pair mutations along the million of allelic bases that make up the human genome. Personal genetic test results include odds ratios for developing a particular disease, condition, or trait, which have been based on the identification of these rare sequence differences that have been correlated in studies with the phenotype in question. It is important to note that these associations are not necessarily causal relationships and that many of these studies are difficult to replicate due to the variability in study protocols, such as in the characterization of the study populations and even the phenotype in question. Nonetheless, genotyping technologies have become increasingly sophisticated and efficient, as SNP analysis is being replaced by new approaches such as whole genome sequencing by which the entire genome is sequenced.

The introduction of DTC personal genetic testing services presents a direct challenge to governance and integration into the health care system. The quickly shifting landscape presents significant challenges to the existing regulatory structure. Concerns over privacy and the confidentiality of genetic information purchased through DTC personal genetic testing companies and (in some cases) bio-banked by these companies, evoke significant social issues about how genomic information may inform individual and group identities, influence reproductive decision making, and raise fundamental questions of who is able to interpret genotyping data and how, and what should be relayed to individual consumers and relatives who may be affected by the information.

Regulating DTC Personal Genetics

The first wave of DTC personal genetic testing companies were launched in the mid-2000s to much fanfare, offering consumers personal genetic information related to ancestry, disease risk, carrier status, and drug responses. At a time when the nation's political forums are dominated by debate about the need to reform our health care system, companies frame their DTC products by building on the public's desire for revolutionary advances in medical care. This discourse, dovetailing with the scientific community's hopes for advancing genetic discovery, has focused on the notion of personalized medicine based on the individual genetic profile. The promise of personal genetics to provide new and effective insights into health care has been a hallmark in the predicted shift toward individualized, preventive medicine.

In the US there has been ambiguity over who should regulate personal genetic testing and how. Laws governing laboratories that may provide genetic testing services include the Clinical Improvement Amendments of 1988, known as CLIA. These regulate the validity of test results and are aimed at minimizing processing errors. Although most DTC personal genetic testing companies will state that they will use CLIA-approved laboratories to process their consumer samples, error in results may still occur. Beyond potential problems with the validity of test results, clinical utility and the interpretation of genotypic data into risk information provided to consumers continue to be largely unregulated in the United States.

A key point of tension for regulators is the challenge by DTC genetic-testing companies to the traditional flow of medical information; it questions the role of physicians and other health care providers as gatekeepers to genetic information. The direct access model is buoyed by the perceived individual right to genetic information and strong claims that direct access is a form of democratization of the genome. Personal genetic testing company *23andMe, Inc.* states on its website, "23andMe believes people have the right to access their personal genetic information. Genetic information is a fundamental element of a person's body, identity and individuality. As such, the rights that people enjoy with regard to financial, medical and other forms of personal information should apply to genetic information as well."

This new model challenges an infrastructure of oversight that is built on the assumption that unlike other types of personal information, genetic information requires gatekeeping. Critical to understanding this shift is the need to determine the nature of the genetic information at stake. *Navigenics*, *23andMe*, and others justified DTC marketing by emphasizing the recreational aspects of their products and asserting that they were not offering clinical diagnostic services. This distinction initially protected DTC companies from direct oversight by the US Food and Drug Administration (FDA), which strictly regulates diagnostic testing for disease risk. Yet, DTC genetic testing companies have toed the line by offering 'risk profiles' for a number of conditions, based on data drawn from GWAS and SNP analysis. Marketing practices that emphasize the potential health-related benefits of the results of these tests, further blur this distinction.

In the United States, the state regulatory bodies of New York and California did not accept this parsing. The New York State Department of Health was specifically concerned about the reliability of the tests and the expectations of uninformed consumers. Citing the discrepancy between the supposed recreational nature of the tests and the health-related nature of the results, the New York State Department of Health sent letters threatening fines and jail sentences to 31 companies who offered genetic testing services without physician involvement. In May 2010, the California Department of Public Health (CDPH) sent 'cease and desist' letters to 13 genetic testing companies forbidding the collection of samples from residents in the State. This was prompted in part by plans by the personal genetic testing company *Pathway Genomics, Inc.* and *Walgreens*, one of the largest pharmacies in the United States to retail personal genetic test kits over the counter in *Walgreens* drug stores across the nation. These plans were abandoned after the FDA demanded a review of the *Pathway Genomics* product and the US Congress convened special hearings to discuss possible industry regulation. Currently, over 20 states limit or prohibit direct-access genetic testing without physician involvement, each variably defining 'direct access' and measures of enforcement. However, unlike other national restrictions on DTC personal genetic testing (such as in Germany, the Netherlands and other European countries) the US has refrained from regulating this industry with national regulations.

Clinical Utility and Health Care Integration

A central focus of debate over the emerging DTC personal genetic testing industry is the value of the genetic information sold and the concept of 'risk' and its interpretation by different stakeholders (the company, the consumer, the physician, etc.). The quality of information provided by companies on how risk is determined varies and relies on classification assignments and assessments of harm that are often left opaque. In addition, these determinations are not equally applicable across the range of phenotypes for which DTC genetic tests are offered. For example, while a false positive or a false negative from a diagnostic test may cause undue harm to a patient, there is no evidence that the same would happen from erroneous results from a DTC genetic test. While the marketing practices of some of DTC personal genetic testing providers may have blurred the lines between diagnostic and recreational information, the risk profiles from SNP analyses derived from the GWAS are not explicitly diagnostic because the results of these studies report on low-frequency alleles in complex diseases. Instead, the genetic profiles generated by these companies represent a general snapshot of future risk for specific conditions rather than definitive indications of whether a customer will or will not develop a disease. As such, most of the test results offered in the DTC personal genetics marketplace consist of information that has minimal clinical impact. There is some worry that there are exceptions, such as tests for mutations associated with Parkinson's and Alzheimer's diseases, which present the possibility of psychological (undue stress or fatalism) or other harm to the consumer, from learning test results.

However, this concept of 'harm,' relating to inexpert action and psychosocial stress in the layperson, has not been empirically demonstrated. One study tested 162 adults with family history of Alzheimer's disease for the apolipoprotein E (APOE)

genotype associated with a higher risk for developing the disease, and compared rates of distress upon learning positive results (Green et al., 2009). The findings of the study showed only a small difference between the participants who received positive disclosure of the APOE genotype and control groups, in respect of levels of anxiety, distress, or depression even one year after the receipt of test results. In addition, a collaborative study by *Navigenics, Inc.* and the Scripps Translational Science Institute that recruited over 3000 adult participants, aged 18–85 years, demonstrated little test-related distress or significant association between risk-assessment scores and changes in behavior such as exercise, fat intake, or total number of screening tests performed. The initial data does not support the notion that consumers are at significant risk of harming themselves if they have access to this information; however, these studies have limitations and more studies of consumer behavior and decision making are needed to examine consumer behavior relating to complex genetic information.

The issue of benefit is also an under-researched area of focus. No individual DTC test has gone through a human clinical trial to demonstrate categorical safety and effectiveness of products from this industry. Given the current regulatory hurdles, it is unclear how such clinical trials would take place as these require significant time and cost. Clinical utility would be very difficult to measure, since the genomic risk assessments are based on an incomplete picture of human genetic variation that provides very basic and partial information about future risk instead of definitive evidence about current diagnosis or prognosis. It is unclear what standards of proof would be required to determine clinical validity. The traditional approach of the 'physician-as-gatekeeper' is challenged by DTC personal genomics. While most medical school curricula now incorporate clinical genetics courses, lack of genetic knowledge by practicing physicians is a systemic problem. Providing risk-assessment information to a doctor who is not qualified or sufficiently informed to explain the results of the assessment to his patient, will not reduce the risk of iatrogenic harm to the lay consumer. Considerations of clinical utility are equally murky. Policies will rely on social study of paradigms of 'harm,' 'risk,' and 'utility,' as they are operationalized by various stakeholders.

Although few national regulations have been enacted to guide the appropriate integration of DTC personal genetic testing with the health care system, several professional organizations have issued policy recommendations that emphasize the need for greater governmental oversight of these tests. The European Society of Human Genetics (ESHG) in its report, *Statement of the ESHG on Direct-to-Consumer Genetic Testing for Health-Related Purposes* recommends that genetic counseling be provided to consumers and that marketing claims be reviewed for accurate information on the test purpose and predictive value. The Human Genetics Commission in the United Kingdom emphasized in 2010, the importance of obtaining truly informed consent by consumers that includes the disclosure of company practices, test benefits, and the limitations of their approaches in providing useful information. In the US, the American College of Medical Genetics, the American Medical Association, and the American Society of Human Genetics all recommended that a qualified health professional supervise genetic testing.

Genetic Ancestry Testing

Personal genetic testing is not limited to tests related to disease or health conditions, but includes what some have referred to as 'recreational genetics.' A significant and growing market for DTC personal genetic testing is genetic ancestry testing. Genealogists interested in reconstructing their family lineage have turned to genetic ancestry testing as an important source of information for tracing their past. This process can focus on the Y-chromosome or the mitochondrial DNA, or mtDNA, inherited through the paternal and maternal lines, respectively. Testing can also probe autosomal DNA to provide results that suggest composition of DNA associated with continental, national, and/or ethnic origin. Numerous companies have proliferated over the past several decades to provide a diverse array of test results to consumers that range in specificity. For example, http://ancestry.com/ might provide customers with results indicating 40% British, 20% Scandinavian, 20% Middle Eastern, and 20% Chinese 'ethnic ancestry' whereas *African Ancestry, Inc.* will provide certificates of ancestry that suggest lineage to a present-day country or ethnic group in Africa. Others will provide 'haplogroups' that are determined by tracing the origin groups associated with specific SNPs. Definitions over what constitutes genetic ancestry can be confusing and be left undefined by companies. An individual's 'geographic ancestry' or 'biogeographic ancestry' can be taken to mean the sum of all the geographic locations inhabited by an individual's biological ancestors. However, genetic data may reveal just a small subset of the full range of ancestors that a consumer may be interested in identifying. For example, knowing a person's Y chromosomal lineage is at best a partial view of an individual's ancestry. There are also concerns over the potential incongruence over what identity may mean. In some cases the individual's or group's self-identification differs from their biogeographic ancestry, depending on a range of historical, cultural, and sociopolitical factors. It is important to recognize that biogeographic information sold to consumers and the cultural ancestry of any individual or group may not be consistent and may present more questions than answers.

A key component of genetic ancestry testing is the quality of the databases used by companies as reference data with which to compare their individual consumer's DNA sample. Although companies acknowledge that mtDNA and Y-chromosome tests provide no information about most of a test-taker's ancestors, more important limitations to genetic ancestry tests are often less obvious. For example, genetic ancestry testing can identify some of the groups and locations around the world where a test-taker's haplotype or autosomal markers are found, but it is unlikely to identify all of them. The underlying patterns of human genetic diversity determine how well ancestry inference could potentially perform. Accordingly, the accuracy of ancestry inference greatly depends on the reference database of populations available. Commercial scientists and private groups often have their own unpublished databases with the potential to provide more refined information than that available from publicly available resources. Yet, even the best databases reflect a woefully incomplete sampling of human genetic diversity, and this has important consequences for ancestry inference.

Research in human genetics has highlighted that there is more genetic variation *within* than between human groups, where those groups are defined in terms of linguistic, geographic, and cultural boundaries. Patterns of variation, however, are far from random. Human population history, including major migrations from one continent to another as well as more short-range movements, has led to correlation between genetic variation and geographic distribution. This finding is particularly true of indigenous peoples; populations characterized by a high degree of interaction with neighboring groups adhere less to these patterns. Inferences of genetic ancestry depend on the samples in a company's database, and even databases with 10 000–20 000 samples may fail to capture the full array of human genetic diversity in a particular population or region. Little is known about the sampling strategies and history of most of these databases. Furthermore, companies are not required to disclose the representation of samples within their databases. As a result, it is unclear whether a DNA sample is identified with a particular African tribe, for example, because segments of Africa are not included in company databases and thus, are effectively excluded from analysis.

An important concept that may be confused in the marketing of genetic ancestry testing is that genetic ancestry is the not the same as 'race.' Human genetic variation within continents is, for the most part, geographically continuous and clinal, particularly in regions of the world that have not received many immigrants in recent centuries. Genetic data cannot reveal an individual's full geographic ancestry precisely, although emerging research has been used to identify geographic ancestry at the continental and subcontinental levels. Genetic clusters, however, are far from being equivalent to sociopolitical, racial, or ethnic categories. Diverse populations identified as 'Hispanic,' for example, are heterogeneous and have distinct ancestries and social histories. Social experiences and conditions inform racial identity, making such identity a poor proxy for genetic ancestry.

Consumers may purchase genetic tests to learn about their race or ethnicity, but there is no clear-cut connection between an individual's DNA and his or her racial or ethnic affiliation. Worldwide patterns of human genetic diversity are weakly correlated with racial and ethnic categories because both are partially correlated with geography and the history of human migration. Current understandings of race and ethnicity reflect more than genetic relatedness, having been defined in particular sociohistorical contexts (i.e., European and American colonialism). In addition, social relationships and life experiences are important components in shaping individual identity and group membership and in some cases, may supercede biological ancestry in significance. Many genetic ancestry tests also claim to tell consumers where their ancestral lineage originated and the social group to which their ancestors belonged. The idea of 'returning to one's homeland' as identified by genetic ancestry information must be treated with care, as modern populations from whom samples have been collected have not over time remained unchanging. Current patterns of residence are rarely identical to what existed in the past, and social groups have changed over time, in name and composition.

Commercial Biobanking and Research

A feature of DTC personal genomics is the development of commercial biobanks using consumer DNA samples for in-house research and/or licensing to third parties. Companies such as *23andMe, Inc.* have amplified the development of such commercial biobanks and suggest that by creating their own large databases from consumer DNA samples, they are well poied to more efficiently 'scale up' for population-based research. Going a step further toward 'accelerating genomic research,' *23andMe* unveiled its new research arm, *23andWe*, in the spring of 2008. Stating that "23andMe isn't just about you," the company advertised *23andWe* as a new model of actively engaging with their consumers offering "customers the opportunity to leverage their data by contributing it to studies of genetics." As a *23andMe, Inc.* customer, you are asked at the time of purchase whether you consent to having your sample and genetic information included in the company biobank. The company states that you may choose to discontinue this relationship at any point; however, once your genotypic information is de-identified of personally identifying information such as your name, address, etc., your information cannot be deleted from the biobank data.

The stated purpose for creating company biobanks articulated by companies like *23andMe, Inc.*, is to facilitate research. Recruitment of human subjects into clinical trials remains a challenge for biomedical researchers, particularly the enrolling of individuals of diverse backgrounds. One *23andWe* research initiative focused on Parkinson's disease through a collaboration with the Scripps Research Institute and the Michael J. Fox Foundation. Individuals diagnosed with Parkinson's disease were recruited and given personal genetic testing free of charge by the company. Research comparing the genotype of those afflicted with the disease and the control group of *23andMe* consumers enrolled in the company biobank led to the publication of SGK1 gene that may be protective against Parkinson's disease in individuals who carry the rare risk-associated LRRK2 G2019S mutation. Based on this research, the company filed a patent on this research in May 2012. Defending the patent, *23andMe, Inc.* argued that the patent was necessary to increase the likelihood that a biotech or pharmaceutical company would pursue drug development and/or other types of research on the disease.

The inclusion practices of DTC personal genetic testing company biobanks create ambiguity on when an individual is being treated as a consumer and when he or she becomes a research participant. Customers, drawn to specific genotyping services by their interest in learning about their own personal data, may be unaware about the implications of donating their genetic data into a biobank for future research. Several scholars have suggested that it will be important for companies to use separate informed consent processes for commercial and research activities, and to establish explicit policies about secondary use of samples. Companies should disclose who would have access to samples and data and the types of research and lengths of time during which samples could be used. In addition, any research using consumer data and samples would require Institutional Review Board (IRB) review of research.

Data Protection and Privacy

One of the major challenges to coordinated research efforts in DTC personal genetic testing companies is the storage and sharing of data across institutions and national borders. There remains great difficulty in obtaining genetic information with highly detailed phenotypic information, and the desire for greater efficiency and utility of genetic data may compete with the ethical concerns of maintaining individual privacy and public trust. Individuals are often sampled in a variety of contexts and although great efforts may be taken to de-identify, encrypt, or de-link personal information, there are substantial fears that the multiple practices through which samples are obtained, stored, and then redistributed for basic research presents serious challenges to maintain anonymity and confidentiality. In their review, Lunshof et al. (2008) list the broad range of possible threats to privacy and confidentiality in genomic research that may occur. These threats include re-identification of individual information after de-identification, which may be implemented by using a combination of surnames as well as genotype and geographical information. Other possible approaches include inferring phenotype from genotype through information such as stature, hair, eye or skin color, or identification of a first-degree relative, in DNA and RNA.

These potential threats are a source of concern for the public. Research indicates that participants are often conflicted. Although they are committed to biomedical research and are comfortable with their information being shared within the medical community, they fear that their information might be leaked. When presented with the choice of restricting access to their information, most participants' concerns over privacy outweigh their sense of altruism participating in research to improve health, and is more likely to lead them to refuse public release of data in data sharing. Current policies make a distinction between information that is solely genetic and genetic information that is accompanied by phenotypic data. In the case of whole genome information, access to genetic information is allowable with specific consent for data sharing. However, if phenotypic information is included, policies recommend only controlled access with specific consent for data sharing. In the case of information on individual gene variants that are included in sets of aggregated data, public access with general consent for future use of genotypic data is possible; however, scholars suggest that when phenotypic data is added to these data sets, they should be subject to controlled access that requires obtaining general consent for future use from participants. Currently, no guidelines on data sharing and privacy protection exist for the DTC personal genetic testing industry.

Geneticization and Human Identity

In a context where the public is bombarded with new information on genetic variants that are asserted to be associated with broad range of conditions from premature baldness to childhood obesity, there is growing potential for the misconception that genetics determines most human conditions and traits. Reports of results from GWAS has furthered ratified the importance of genes and oversimplified understanding of complex human diseases through enlargement of the potential role of any one genetic variant. Aside from the rare, single-gene disorder such as Huntington's disease, genes often play a limited role in the pathophysiology of complex human conditions and traits such as diabetes, coronary heart disease, and asthma. Single genes are most often mediated by other genes, interacting with environmental factors in multiplicative ways that may ultimately affect an individual's likelihood to develop a specific phenotype.

The significance placed on genetics is easily understood within the context of our technoscientific culture. The gene has become a powerful symbolic icon in our society in which genetic information is believed to be uniquely identifying, holding great significance for individuals in defining who and what they are. The clichéd explanation of 'it must be in their genes' for individuals displaying unusual musicality or athleticism reveals the entrenched view that certain human traits are destined in our genetic code. In translating human genetic variation research into clinical decision making and individual health practices it will be equally important to study the impact of the ubiquitous circulation of genetic information on conceptions of humanness and identity.

Concern for groups such as American Indian tribes, are behind efforts to explain origins by genetic ancestry information without regard to the cultural, religious, social, historical, and political processes that also inform group origin, membership and identity, and access to group rights. Some related issues include the use of genetic ancestry information as the basis for: changing one's identity on various government forms; making claims to certain group rights or benefits; and for immigration purposes, such as seeking dual citizenship. These issues are of increasing practical concern and likely to become more so in the future.

Among the most pervasive and pernicious claims of genetically determined traits are theories on the racial ordering of intelligence. Despite the weak scientific basis for such ordering, the consistent return to the rhetoric of racial hierarchies of IQ reflects the powerful role that science has historically played in promoting racist ideologies. Current evidence suggests that for most complex behavioral traits, contribution of any one gene to normal variation is small and these traits may be more fully explained by variation in environmental factors. It is important to caution against making the naive leap to a genetic explanation for group differences in a complex behavioral trait, where environmental and social factors clearly can and do play major roles. These issues are particularly important, as personal genetic information becomes readily available through DTC personal genetic testing services and the general public faces the challenge of rendering genetic data meaningful.

Disabilism

Elizabeth Lightfoot, University of Minnesota, Saint Paul, MN, USA

© 2015 Elsevier Ltd. All rights reserved.

Abstract

Despite the widespread adoption of national and international policies banning disability discrimination, people with disabilities still experience various forms of disability discrimination known as disablism. While disablism is pervasive, the concept of disablism is less familiar among the mainstream audiences than similar concepts like racism and sexism. The profession of social work, with its core value of social justice, has an important role to play in reducing disablism in society. However, the social work profession has its own history of institutional disablism related to the medical model orientation to service provision. The profession of social work can begin to address disablism through focusing on increasing disability awareness within the profession, adopting an anti-oppressive practice approach, and embracing innovative social-service innovations that reduce disablism, such as self-directed supports, person-centered planning, and universal design.

Introduction

Roughly 15% of the world's population, or 650 million adults, have some sort of disability (WHO, 2011). About 80% of people with disabilities live in developing countries, which have a higher prevalence rate of disability due to poor medical care, lack of access to immunizations and other preventative measures, and poor nutrition. (This article uses people-first language – 'person with a disability.' However, the author acknowledges that many people with disabilities view 'disabled person' as the more appropriate language and encourages social workers to use the language desired by people with whom they are working.) Disability is more common among people over age 50 due to age-related disabilities. The high prevalence rate of people with disabilities means that social workers practicing in any subfield of social work are likely to work with people with disabilities.

In the latter part of the twentieth century, there was growing awareness worldwide that people with disabilities experienced specific forms of discrimination and exclusion from mainstream society, and faced physical, legal, attitudinal, and other barriers to participation in regular life activities (Barnes, 1991). Disability activists began to form national and international movements demanding policies that eliminated discrimination and provided services and supports. Consequently, many nations have now adopted antidiscrimination laws banning various types of disability-related discrimination. Routine types of disability discrimination that have been banned include discrimination in employment, housing, education, public services, transportation, and places of public accommodation, including stores, restaurants, or personal services. Some of the earliest national antidiscrimination laws were the United States' Americans with Disabilities Act of 1990, Australia's Disability Discrimination Act of 1992, and the United Kingdom's Disability Discrimination Act of 1995, while Canada had included a stipulation against disability discrimination in its Constitution back in 1982. Many other nations adopted similar types of antidiscrimination laws in the 1990s and early 2000s, and the United Nations formally adopted the Convention on the Rights of Persons with Disabilities in 2006 that entered into force in 2008. As of 2012, 169 countries have formally ratified this Convention (United Nations, 2012).

Though the concept of disability discrimination is now more widely understood, there is no commonly agreed term for disability discrimination similar to racism for race-based discrimination or sexism for gender-based discrimination. The two most common terms are disablism and ableism, although their use in mainstream society varies according to country. This article first introduces disability definitions and models, and then discusses disablism in the context of social work practice.

Disability Definitions and Models

Understandings of disability vary according to culture, country, gender, philosophical orientation, religious values, region, and prevailing societal attitudes. This has resulted in the lack of a standard definition of disability. Common definitions of disability include disability being defined as a person having a diagnosis with a particular condition or disease, such as cerebral palsy, Down syndrome, blindness or Huntington's disease; or disability defined as a person having a functional limitation, such as a limitation in walking, standing, thinking, seeing, or hearing. Disabilities are often categorized by type of disabilities, such as physical disabilities, sensory disabilities, or health-related disabilities. The categories of disability are called by different names in different countries. For example, in the United States, a person with a cognitive limitation, such as Down syndrome, is said to have an intellectual disability, while in the United Kingdom the person is said to have a learning disability. Disability within the disability rights movement has typically been defined broadly, including a wide range of categories of impairments. Thus, the broad umbrella term of disability includes people with intellectual/learning disabilities, sensory disabilities, physical disabilities, and mental health disabilities. Because there is not clear objective reality related to disability, the concept of disability has been referred to as 'socially constructed' (Liachowitz, 1988), 'socially created' (Oliver, 1996), or simply an 'administrative category' (Stone, 1984).

The World Health Organization developed an International Classification of Functioning, Disability and Health (2001), commonly referred to as ICF, to categorize disability beyond the concept of disease and disorder. This categorizes disabilities or health conditions in three ways: impairments a person has within their body, for example, those related to pain, cognition, or mobility; activity limitations, such as a difficulty walking or eating; participation restrictions related to discrimination or physical barriers. The ICF aims to be a universal classification of disabilities, which can be used to understand disability worldwide.

Models of Disability

Disability is often understood from different lenses referred to as models of disability. The main disability models are the medical model, the social model, the independent living model, and the minority model. These models represent more than just theoretical classifications of disability, but rather identify differing real-world understandings of disability that have directly shaped the experiences of people with disabilities. The models are not mutually exclusive, though the social, independent, and minority model contrast with the medical model.

Medical Model

The medical model of disability is the dominant twentieth and twenty-first century model for understanding disability among many professionals, and public perception of disability often reflects this model. In medical model, disability is seen as a pathological individual attribute linked to incapacity and dependence. A disability is defined by the presence of any functional limitation in daily life that are caused by a physical, mental, or sensory impairment. This model is rooted in the functionalism of Talcott Parsons (1958), in which people with disabilities assume the 'sick role' in society, thereby becoming exempted from normal social activities (DeJong, 1979; Parsons, 1958). Thus, people with disabilities must rely on professionals to help them recover, cope, or rehabilitate from their impairments (Hahn, 1985). The subtext of the medical model is that people with physical, sensory, or mental impairments have a tragic flaw and need expert help to overcome this flaw. The focus is on the pathology of an individual, without focus on the connections between that individual and society, or the environmental barriers that individuals with disabilities face (Brisenden, 1986). Health care and other professionals pervasively use the medical model when providing services to people with disabilities, and the institutional structures for providing services commonly reflect the medical model approach.

Social Model

The social model of disability focuses on the social construction of disability. According to the social model, while individuals may have a physical, sensory, or mental impairment, it is the failure of society to accommodate a range of impairments that results in 'disability.' This model was developed in the United Kingdom in the 1970s in response to the inadequacies of the perceived methodological individualism of the medical model of disabilities (Oliver, 1983). The social model argues that the divisions between disability and ability are socially constructed, and that this social construction is a middle range consequence of the economic and social forces of society. Disability is not a problem of the individual that must be overcome, as suggested by the medical model, but rather a result of multiple barriers created by society. People with disabilities experience societal oppression based on these societal barriers. The proponents of the social model also argue that a society's political and economic mandates reinforce the need for a category of dependents, with large bureaucratic structures and institutions perpetuating themselves by serving people with disabilities (Oliver, 1996). While the social model has been critiqued as neglecting gender (Morris, 1992) and being too rigid (Shakespeare and Watson, 2002), the social model of disability has become the predominant model for understanding disability among disability activists worldwide and is the underlying conceptual framework of the ICF. Many social workers working with people with disabilities now use the social model of disability and work to reject the medical model structures inherent in some forms of social work practice.

Independent Living Model

The independent living model arose in the United States in the 1970s at the same time as the social model, spreading swiftly throughout much of the world, and, like the social model, has influenced the international disability movement. The independent living model, first articulated by DeJong (1979), was developed in response to the medical model. The independent living model views disability as more than just a medical condition or an impairment, but as an interaction involving the individual, the society, and the environment. This model of disability views the role of professionals and government in the lives of people with disabilities as a key issue (DeJong, 1979). The solution to this problem is for people with disabilities to gain independence from professionals, and thus the independent living model has a strong emphasis on self-help and individual or consumer control of services as an antidote to the problems associated with impairments. The independent living model does not maintain that people with disabilities are able to do everything for themselves, but rather that they should have control over their lives and be able to make the decisions on how and when they receive support (Brisenden, 1986). The independent living model led to the development of an international network of self-help organizations run by people with disabilities, Centers for Independent Living.

Minority Model

The minority model of disability, articulated first by Hahn (1985), views environmental barriers as the principal barriers to participation in community life by people with disabilities, with discrimination playing a central role in their being denied access to jobs, buildings, and the community. The minority model views people with disabilities as a socially constructed minority group because of the shared discrimination they face,

and thus people with disabilities are similarly situated as racial and ethnic minorities and women. Similarly to the independent living model, the minority model views professionals, such as social workers, as having too much power over the lives of people with disabilities because this strips them of their independence (Gliedman and Roth, 1980). Drawing from his minority model, the civil rights approach focusing on passing antidiscrimination legislation is seen as an appropriate solution for people with disabilities to overcome barriers.

Disablism and Ableism

While there is no globally accepted term to define disability discrimination (Harpur, 2009), the two terms most often used are disablism and ableism. These terms are not equivalent, and their use overall in mainstream society is limited in comparison to racism and sexism. Usage varies according to country. For example, in Australia, ableism is more commonly used. Disability activists also disagree about which terminology is most appropriate and less oppressive.

'Ableism' refers to the belief that certain normative understandings of ability are preferential to others. Wolbring (2008) defines ableism as "a set of beliefs, processes and practices that produce – based on abilities one exhibits or values – a particular understanding of oneself, one's body and one's relationship with others" (pp. 252–253). The concept of ableism is more broadly focused than typical understandings of disability, as ableism refers to beliefs about any person who does not meet societal norms of ability, whether or not they have a disability (Wolbring, 2008; Harpur, 2009). However, the term ableism is typically used in the context of disabilities. Ableism in the context of disability means that certain physical, cognitive, sensory, or other types of abilities are preferred, and people who have differing abilities are considered impaired. Ableist views would regard someone who does not fit the ableist vision of society as someone who needed to be fixed. Ableist views of society in which certain abilities are valued over other abilities lead to the development of political and social structures that value these abilities. These ableist views are used by many to consciously or subconsciously justify unequal treatment of people with disabilities (Wolbring, 2008). Some have critiqued the term ableism as being derived from a medical model understanding of disability, as it could lead to a focus on individual ability rather than oppression (Withers, 2010). However, it does not appear that this is the intention, rather it is a term that is in line with the terms racism and sexism. Ableist beliefs about certain abilities lead to disablism, or discrimination against people who have disabilities.

The term 'disablism' describes negative beliefs and discrimination based on disability, focusing on the societal oppression faced by people with disabilities. Miller et al. (2004) define disablism as "discriminatory, oppressive, or abusive behavior arising from the belief that disabled people are inferior to others" (p. 28). People with disabilities experience disablism when they are excluded from participating in society through various types of barriers, when they are viewed as objects of pity, or when they are exhorted to overcome their disability. Disablism can occur at different levels. Individual-level disablism involves personal negative beliefs that individuals have about people with disabilities. Institutional disablism refers to the development of societal structures or institutional practices that leads to the systematic exclusion of people with disabilities. This can lead to additional social and physical barriers for people with disabilities. Some have critiqued the term disablism for placing the focus on the person with the disability or disability itself, rather than the discriminator or the act of discrimination (Harpur, 2009). Nonetheless, disablism is the preferred term for disability-related discrimination among many disability advocates, and is the term of choice in Great Britain. While the terms ableism and disablism have slightly different meanings, both terms convey an understanding of the types of societal discrimination that people with disabilities experience based on negative views toward people with disabilities.

While disablism focuses primarily on disability-related discrimination, people with disabilities have multiple social identities, and often experience what is known as multiple oppression based on their memberships in other oppressed or marginalized groups (Vernon, 1998; Lightfoot and Williams, 2009). For example, an African-American with a disability can experience racism when interacting with people with disabilities, disablism when interacting with African-Americans, and potentially both racism and disablism when interacting with others. Likewise people with disabilities can experience multiple oppressions related to gender, sexual orientation, class, age, national origin, religion, or other oppressed statuses, and experience multiple dimensions of exclusion. People with disabilities sometimes feel as if they have to choose between their identities (Lightfoot and Williams, 2009) and find no home in any one movement.

In the last several decades there has been a new emphasis on the intersectionalities between disability and other social categories, such as gender (Morris, 1992; Shakespeare, 1999), mothering (Lewiecki-Wilson and Cellio, 2011), congenital vs acquired disability (Shuttleworth et al., 2012), and body image (Wendell, 1996). For example, much has been written on the conflict between masculinity and disability as being in conflict with each other (Gerschick and Miller, 1994; Shakespeare, 1999; Shuttleworth et al., 2012), as masculinity is associated with autonomy and power, while disability is associated with dependency. These deeper understandings of intersectionalities give a better understanding of the contexts in which disablism occurs.

Disablism in the Field of Social Work

The field of social work has a complicated history with regard to disablism. Many social workers have worked hard at reducing disablism within society and have been leaders in the disability rights movement. However, social work as a profession has often been faulted for helping to perpetuate ableism and disablism by adhering to the medical model of disability (Mackelprang and Salsgiver, 1996; Meekosha and Dowse, 2007). Additionally, the field of social work historically played only a peripheral role in the disability rights movement, and has paid less attention to disablism, ableism, or disability discrimination than would be expected for

a value-based profession. Social work practitioners need to understand the relationship between the profession of social work and disablism when working with people with disabilities.

One of the key criticisms of the field of social work in relation to people with disabilities is the role social workers have played within the medically oriented system of disability services and supports. The field of professional social work in the twentieth century developed simultaneously with both the development of some types of services and supports for people with disabilities in many countries. Social workers, along with physicians, nurses, and other professionals, often are in positions where they assess the needs of people with disabilities to determine the types of services for which a person with a disability is eligible. The social worker often plays the role of 'expert' in the life of a person with a disability, serving as a key gatekeeper between a person with a disability and any services or supports he or she might need. The person with a disability is put in a position of dependency, as the person with a disability becomes dependent on the social worker to receive services and loses the opportunity to make choices regarding his or her own life (Mackelprang and Salsgiver, 1996; Meekosha and Dowse, 2007). Even the whole notion of social work as a 'helping' profession implies that people with disabilities need to be helped by others, situating social work squarely within the medical model approach to understanding disabilities. While social workers working with people with disabilities can and do work to eliminate disablism with the system, and this is more prevalent in some countries, the structures in which some social workers practice promulgate disablism.

Historically, social workers have been involved in making decisions about the lives of people with disabilities that people with disabilities might not have chosen for themselves. For example, social workers were often involved in decisions to institutionalize people with disabilities without their consent, to sterilize people with disabilities, or to remove infants upon birth from their parents with disabilities based on their disability diagnosis. These types of actions by social workers clearly could be categorized as disabling. However, even the seemingly benign social work tasks of assessing and determining eligibility for services can be considered disablist, when the social worker as expert has the last word in determining eligibility. Likewise, the emphasis on developmental or program plans for people with disabilities, which are common for social workers when working with people with disabilities, could also be seen as disablist. In such plans, people with disabilities often are given goals to work on for self-improvement, such as reducing negative behaviors. This type of approach could imply that people with disabilities must work on overcoming their disability, rather than focusing on accepting a person's impairments and working on reducing societal barriers. A disablist system is not the fault of the individual social worker, but rather the system often requires the social worker to play the role of policy enforcer or gatekeeper. This has resulted in some people with disabilities viewing the social work profession with suspicion (Mackelprang and Salsgiver, 1996; Beaulaurier and Taylor, 2001).

While there were some social workers involved in the disability movement from its beginning and many social workers are now involved in the front lines of the disability movement, the field internationally has been somewhat ambivalent in its stance on disability discrimination and disability rights and as a whole has not embraced the disability rights movement in a similar fashion as it embraced the civil rights movements of other oppressed groups in many countries. In fact, the disability rights movement in the United States in particular and also in the United Kingdom started partially as a reaction to having professionals, such as social workers, having control over the lives of people with disabilities (Beaulaurier and Taylor, 2001). Groups of people with disabilities started their own organizations that were distinct from organizations that others organized for people with disabilities, such as groups that were run by or dominated by professionals. These groups of people with disabilities, such as Centers for Independent Living, often focused on radical self-help, where people with disabilities determined and controlled their own services and supports without professionals being involved. Despite the efforts of some social workers to become allies in the disability movement, social workers in general were not seen as natural allies to the movement, and the field of social work was not active in causes fighting for antidiscrimination laws or eliminating disablism within society (Mackelprang and Salsgiver, 1996). While social work's self-purported values include an emphasis on social justice and empowerment, disability has not been a core focus of social work in many countries, such as the United States and Australia (Meekosha and Dowse, 2007). In these countries, compared to other fields of social work practice, there are fewer social work students, educators, researchers, and practitioners interested in disability and involved in disability activism in comparison to other fields of social work (Mackelprang and Salsgiver, 1996).

Addressing Disablism Social Work and Social Work Practice

Social work, with its core value of social justice and its ecological and systems understanding of society, has an important role to play in reducing disablism and ableism in society. However, social work needs to address disablism, ableism, and disability discrimination within the profession and in the nature of service delivery. There have been great strides in the past few decades in reducing the disablism within social work and the disablist nature of the provision of services and supports. Below, I consider some of these efforts.

Reducing Disablism within the Social Work Profession

Disability Awareness among Social Workers

As the social work profession has had a role in disablist society, the first step for social workers in addressing disablism in society is through reflection and change within the profession. There has been a lack of awareness among social workers about disability in general, and the concepts of disablism or ableism. For example, social work education in the United States has typically not included a strong focus on disability, and though

content on disability discrimination and disability-related oppression is required in all social work programs, when disability is discussed within social work education it often focuses on diagnosis and service provision, thus reflecting a medical model orientation (Gilson and DePoy, 2002). Social work students, who are not presented with the social, minority, and independent living models of disability and are not given the opportunity to grapple with the concepts of disablism or ableism, miss the opportunity to reflect upon the historical role social work has played in the lives of people with disabilities. Even when disablism is commonly discussed in social work education, as in the United Kingdom, the reality of social work practice being dominated by the medical model in the United Kingdom hospital settings makes the need to grapple with this content in an in-depth manner during social work training crucial. Increasing disability awareness among social workers through social work education is vital for reducing disablism in social work.

Anti-Oppressive Practice

The movement toward anti-oppressive practice is another step toward reducing disablism within the social work profession. Anti-oppressive practice is an approach to social work in which social workers align themselves with oppressed people, with the intent not only to eradicate social injustice, but also to eliminate social work's role in perpetuating oppression (Dominelli, 2009). Dominelli (2002) argues for a holistic approach to oppression that does not place different kinds of oppression in a hierarchy and that deals with individual needs and structural change – both inside and outside social work. Anti-oppressive practice requires social workers to understand, recognize, and work to reduce power imbalances (Dalrumple and Burke, 1995), which are especially stark within a disablist society. An anti-oppressive practice approach would necessarily require social workers to align themselves as allies with not only the recipients of services, but also the disability rights movement overall. Adopting anti-oppressive practice in social work would essentially entail social workers forsaking the medical model understanding of disability, and relinquishing their role as experts in the lives of people with disabilities. As the disability rights movement has embraced a self-help approach to services and has rejected the paternalistic role of professionals, including social workers, in their lives, an anti-oppressive practice approach might be one way for social workers to align themselves with people with disabilities. Social workers engaging as allies need to be critically self-reflective in their work to be sure they do not replicate their positions of power when connecting with people and groups of people with disabilities.

Reducing Disablism in the Delivery of Services and Supports

The nature of the delivery of services and supports for people with disabilities also can reproduce disablism in society. Fortunately, there have been innovations in the structure and nature of disability services that can lead to people with disabilities having more control over their lives and being less dependent on professionals. Some of these innovations include the rise of self-directed or consumer-directed services, person-centered planning, and universal design of services.

Self-Directed or Consumer-Directed Services

At the onset of the disability rights movement in the 1970s, people with disabilities advocated for independence from professionals, such as social workers, who were controlling most aspects of their lives, including where they lived and who provided them with services. When agencies direct services, professionals like social workers often determine not only the type of services that a person with disabilities might receive, but also the particular personnel who will provide these services. Many countries have now adopted self-directed or consumer-directed services, which are a type of service arrangement where people with disabilities use governmental funds to hire their own services and supports (Mahoney et al., 2000). For example, in the United Kingdom, most people with disabilities are able to receive direct cash payments in the place of social services or supports that they used to receive through the government. These cash payments must be used on their own care needs, but the person with a disability is responsible for obtaining these services, including hiring their own personal assistants (Glasby and Littlechild, 2009). Personal budgets, which have even more flexibility or now available in a number of countries, including the United Kingdom, the Netherlands and Canada. Under this arrangement, a social worker's role changes from being the expert in the life of the person with disability to being more of a broker of services and facilitator of self-advocacy (Mackelprang and Salsgiver, 2009). By allowing a person with disability to control the services they receive, the self-directed approach helps to reduce the disablism that people with disabilities experience in their encounters with the social welfare system.

Person-Centered Planning

Person-centered planning is another advance in supporting people with disabilities that works to empower people and reduce the disabling nature of the social welfare system. This approach arose in the field of intellectual disabilities and has been used for decades (O'Brien and O'Brien, 2001). Person-centered planning is a process in which people with disabilities and their families plan for their future based upon the person's own desires. This phenomenological approach begins with understanding a person's own version of reality, and then planning and developing supports and services that best help the individual to meet his or her own goals. It differs from traditional social work assessment in that it is not services focused or needs focused, and involves structured exercises in which people who know the person with the disability best, typically not just professionals, but also family members, friends, neighbors, and others, provide input. Professionals, such as social workers, play the role of facilitator and information and resource provider, rather than expert.

Universal Design

Another approach to reducing disablism in service delivery is the incorporation of the concept of universal design as much as

possible into society in general, as well as in social welfare service delivery. Universal design is an approach in which accessibility for people of all ages and abilities is included in the initial design (The Center for Universal Design, 1997). Universal design was originally used in the context of architecture. If buildings or public spaces were initially designed to be accessible, such as by incorporating ramps, wide doorways, and other accessible features into the initial design, then people with disabilities would face fewer barriers to participation and there would be less need for people with disabilities to have to ask for accommodations. The concept has since been applied to programs and services as well, with the concept being used extensively in the area of education. For example, in universal instructional design in higher education, the format of courses is varied to attempt to provide as universal access as possible for students with varying types of needs, such as language abilities, family situations, cultural background, or abilities. This might include using varied instructional methods, incorporating natural supports, and providing flexible means of evaluation (Lightfoot and Gibson, 2005). Universal design explicitly rejects ableist notions with the intent of designing structures or services for people with as diverse a range of people as possible. The shift toward universal design at the initial design of programs can take the focus away from disability and make it the responsibility of program designers to minimize barriers to participation. While social welfare services have not extensively adopted universal design principals, incorporating components of universal design into the structure of social welfare services can help reduce disablism.

Disability Activism

Finally, if the social profession is interested in reducing disablism in society, it must ally with the disability movement and disability activists to work together to reduce societal barriers that people with disabilities face; change disablist policies; improve service delivery models and supports; foster empowerment of people with disabilities; and change societal attitudes about disability. Disability activism fits well within the social justice framework of social work.

Disability and Disabling Practices

Tania Jivraj and Esther Ignagni, The School of Disability Studies, Ryerson University, Toronto, ON, Canada

Published by Elsevier Ltd.

Abstract

This article provides an overview of the interdisciplinary field of disability studies. It highlights the social model of disability, a foundational analytic framework within disability activism, practice, and scholarship. Through explicating and historicizing the emergence of disability as a social category, the article offers the social sciences an emancipatory lens through which to reflexively examine and dislodge disabling assumptions and practices. The article concludes by illustrating how disability studies can complement and expand the social justice orientations of contemporary social science research and practice.

Disability studies is a relatively new and burgeoning interdisciplinary field. Emerging from and intertwined with the efforts of disabled activists, the field has been critical from its inception, and remains committed to a process of reflexive revision and extension. The official definition adopted in 1993 by the Society for Disability Studies notes, that "Disability Studies [seeks] to disentangle impairments from the myth, ideology and stigma that influence social interaction and social policy" (Society for Disability Studies, n.d.). Further, "[D]isability studies holds that disability is a complex political and cultural effect of one's interaction with an environment, not simply a medical condition to be eliminated" (Dolmage and Lewiecki-Wilson, 2010: p. 30).

Disability studies, similar to other scholarly equity projects, 'cuts across a range of disciplines' – from medicine and psychology to art and philosophy to education and social work – to examine how power and privilege function to create and reproduce ableist cultures (Mallett and Runswick-Cole, 2014). Ableist cultures are constituted by two prevailing systems of thought. The first constructs disability as an inherent deficit or anomaly of the individual and the second promulgates compulsory able-bodied and reasoned normative standards to which we must all aspire (Campbell, 2008; McRuer, 2006). Together, these systems conspire to justify and structure the marginalization of people who live with or who are presumed to have impairments (Stevens et al., 2011). In challenging assumptions of the normative body, disability studies scholars begin their work in the experiences of people who live or are labeled with impairments to analyze, critique, and reimagine social, political, and legal phenomena. As the Canadian disability rights activist and scholar Catherine Frazee (2003) has noted:

> … disability studies "takes for its subject matter not … [particular] variations … in human behavior, appearance, functioning, sensory … and cognitive processing, but the *meaning* we make of those variations" (Linton, 1998, p. 2). According to Simi Linton (1998), it is "a field that explores the critical divisions our society makes in creating the normal versus the pathological, the insider versus the outsider, or the competent citizen versus the ward of the state" (p. 2). The project of Disability Studies, according to Peter Monaghan, is to "pull apart concepts about disability to see what cultural attitudes, antagonisms, and insecurities went into shaping them" Monaghan, 1998: pp. 15–16.
>
> Frazee, 2003: p. 258

Thus, transforming current conceptualizations of the disabled body (and mind) as one to be pitied, to be cured, to be contained, and to be hidden to one that recognizes disability as a political and cultural identity formed from our responses to differences, where difference is unquestioningly and routinely pathologized.

Disability studies embraces an agenda for social transformation. Throughout its short history, disability studies has called for a broader, more inclusive conception of human rights (Harpur, 2012; Peters, 2008). More radically, materialist proponents within disability studies call for the replacement of disabling capitalist economies with inclusionary alternatives (Tregaskis, 2002). Recent expansions of the field illuminate how 'disability is a teacher' (Titchkosky, 2003), how disability can be an 'occasion to see the world otherwise' (Schormans, 2013), and how disability generates new ways of making interdependent communities, calling the bounded individualized neoliberal self into question (Goodley, 2014).

A Word about Language

There is no one definition of disability. Rather, disability is understood in a variety of ways depending on the field of study or profession. In this article, disability refers to the complex interplay of how social, economic, cultural, and historical events construct an experience of disablement. Just as the term disability is contested, so to is disability as an identity. It is important to state that there is no essentialized disabled identity, since people living and labeled with impairments have complex and intersecting identities that simultaneously mitigate and exacerbate how their disablement is experienced (Rosenfeld et al., 2006). I alternatively use the terms disabled peoples or people living and labeled with impairments. The former reflects language borne of the social model of disability that recognizes that our environments disable people rather than situating the disability in the individual. Thus people may live with impairments, but are disabled through the exclusionary social and physical arrangements of our worlds that systematically fail to account for impaired bodies and minds. Finally, the phrasing 'individual labeled with an impairment' reflects constructivist understanding, with the focus being on the 'labeled with' rather than the person or the disability. In this way, I am acknowledging that people are acted upon by external forces that form how they are understood in their society.

Why Is Disability Studies Relevant to Social Work?

> Although social work has a rich history of advocacy for oppressed people, the profession has been hesitant to become involved with people with disabilities.
>
> Mackelprang and Salsgiver, 1996: p. 7

Current social work practices and education surrounding disability are steeped in ideas of the disabled body needing to be fixed and the disabled person needing sympathy and help (Profitt, 2010). The repercussions of this ideology of disability as a personal deficit can include segregation, intrusive state control, and limited access to a public life. In this article, we use principles taught in disability studies to lay the groundwork for an expanded understanding of disabilities that will hopefully support social workers to question their own biases about disabilities, so that we may not inadvertently engage in discriminatory professional practices that further disable people.

Though the role of social workers is vast and varied, a core of the profession is that we work to promote equity and inclusion of marginalized populations. This work of equity is particularly salient when we consider that disabled peoples are more likely to be discriminated against in terms of employment, housing and access to education, and more likely to be victims of violence (Chenoweth, 1996). This discrimination, or ableism, is based on the presumption of disabled bodies as incapable, dependent, and broken. The World Health Organization does not particularly name ableism as a factor when it states that "people with disabilities have worse health and socioeconomic outcomes … lower education achievements, less economic participation and higher rates of poverty than people without disabilities" (World Health Organization, 2011: para 6). Ableism is inferred when "negative attitudes" (para 6) and "lack of service provision" (para 6) are listed as barriers to full inclusion. As social workers, it is imperative that we work with disabled peoples to transform these structural and attitudinal barriers. Especially as we may work in organizations whose foundations are based on the medical model of disability.

The conscious act of challenging preconceived notions of disabilities is part of the work of disability studies. Disability studies seeks to challenge the oppression of disabled peoples by exposing multiple understandings of disabled identities as a part of the human spectrum of difference and the cultural meanings ascribed to those differences.

From a practice perspective, it is vital that as service providers we reflect on our assumptions of the meanings we make of disabled bodies in order to

1. challenge a cultural conflation of ability with humanity,
2. not further oppress already marginalized populations,
3. recognize the knowledges embodied in disabled experiences,
4. support ally-ship, community building, and political action,
5. change our own lives as we understand how labels of disability are a form of social control and surveillance for all bodies (living in fear of our own potential impairments and disability), and
6. reap in the benefits of a more just society and alternatives to being that can liberate us all.

The Construction of Disability in Western History

Our contemporary understanding of disability can be historically and geographically situated in many ways; Western activists and scholars tend to begin their analysis with the rise of industrial capitalism (Barnes, 2010; Oliver, 1990). Industrial capitalism's profound influence on the fabric of social and economic life created the conditions under which impairments were socially produced. New industrial disciplinary regimes led to a new emphasis on individual productivity, efficiency, and effort, in turn producing new forms of exclusion. Large numbers of the population who could not readily keep up with or accommodate themselves to the physical (and mental) demands of industrialization found themselves excluded from work. Furthermore, the repetition, speed and duration of industrialized work practices, dangerous work conditions (poor air quality, crowding, equipment failure, lack of safety practices/equipment, etc.), and meager remuneration conspired to 'break-down workers' bodies and minds. Thus, there were more people with impairments, and considerably more disability. Those who could not find a 'productive' place within industrial economy quickly became destitute. As the ranks of those who could not sustain employment within the industrialized economy swelled, governments faced a new problem – what to do about the large numbers of people living in dire poverty. In rural communities, those who could not work were cared for in the home – but with the changing family structure, the 'workless' had to turn in growing numbers to charity. Governments feared civil unrest and criminal activity, as well as the draining of public coffers as the ranks of the unemployed and poor grew. Warehousing and classification of the poor was tasked to the newly formed Poor Law Commissions, who sought to contain and regulate workless people through dividing practices (Skeggs, 2014). Crucially a system of classification emerged to distinguish between the legitimate and the illegitimate recipients of state benevolence; however, an objective index to measure capacity to work was required for its maintenance. By the early nineteenth century, medicine was well equipped to assume this powerful role. Louis Pasteur and others had discovered the germ theory of illness and disease; new technology such as the X-ray, the microscope, and the stethoscope allowed for the precise measurement required in the welfare state. This new technology allowed experts to dissect the human body into various functional units that could be individually measured. Medical methodology was positioned as objective, scientific, and empirical. Medical science was therefore incorporated as an apparatus of the state, with doctors as gatekeepers to social welfare (Barnes et al., 1999; Frazee, 2003). These experts then deemed that the bodies of people with impairments, children, and the elderly were considered incapable of working (Frazee, 2003; Oliver, 1990).

This gatekeeping function has remained remarkably durable. Social workers still defer to medicine to legitimate access to welfare disbursements, specialized equipment, vocational training, and adapted living arrangements (Nathan and Webber, 2010). In this way, service providers in social service support agencies depend on the legacies of medically determined knowledges about disabled peoples to also act as gatekeepers. Social workers in effect can be considered as extending the practices of legitimation in determining which bodies will receive support and which ones will not such that disabled persons experience medicine as a site of misplaced authority. The medical model and the institutions upon which helping professions are built wield a great deal of power and control over fundamental aspects of our lives. And, as Michael Oliver (2009) notes, they:

> have not been noticeably reticent about using this power to make decisions about … where [we] should live, whether [we] work or not, what kind of school [we] should go to, what kinds of … services [we] should receive and in the case of unborn disabled children, whether [we] should live or not (p. 24).

Medicalizing disability assumes a problem in individual functioning that supports the dominance of a 'normal' body rather than an examination of how normalizing processes are a way of pathologizing differences. Without additional models with which to engage in disability politics, social workers are at great risk of engaging in oppressive interventions and practices. Disability studies contends that this history of medicalization of disability in service of capitalist interests has given rise to the medical model of disability.

The Medical Model of Disability

The medical model is founded on the belief that behaviors and bodies can be objectively measured (Lewis, 2006). These measures then lead to the categorization and diagnosis of people's experiences and bodies. These diagnoses in turn enable helping professionals to provide treatments to assist disabled people to fit into a normalized able-bodied society. It is the assumption of a correct and normal body that supports the construction of disability as abnormality (Frazee, 2003). Dichotomies, such as normal versus abnormal, able-bodied versus disabled, and competent versus dependent, are the cornerstone of the medical model (MacKay and Rutherford, 2012). Thus if to be normal is to be independent, capable, and healthy, the medical model conceives of disability as the antithesis – dependent, diseased, broken, pitiable, incapable: both a problem of lack and excess (Goodley, 2011). This adherence to medicalizing human differences against a subjective norm is the basis of the medical model of disability. This deficit model of human variation presumes a problem and that problem *is* the individual. From this place of deficit, the person becomes a site for expert intervention as their bodies are placed in the care (or control) of those in the helping professions.

The medical model has a reach that extends beyond medical institutions and the medical profession. It forms the structure upon which many helping professions are developed. Social work practices that assume the medical model as their foundation for working with disabled people, to the exclusion of other models, then value or devalue people's bodies as they are measured against a predetermined standard. Those who do not meet those standards are understood as impaired and in need of clinical intervention.

How Can Disability Studies Challenge Normative Assumptions of Disabled Bodies?

However, the medical model is but one way to consider human variations and differences. Starting in the work of UK-based disabled activists (and social workers) a 'big' and 'emancipatory idea' emerged. The idea held that the deprivations of our lives were not the inevitable consequence of our various conditions of physical or mental impairment, but rather result from discriminatory social arrangements and arbitrary practices of exclusion (Goodley, 2010). An argument was formulated that disability is situated not in individual pathology, but in "society's failure to embrace diverse ways of being in the world – that disability is extrinsic rather than intrinsic" (Frazee, 2003: p. 260).

In the terms of 'on-the-ground' activism, to be disabled no longer means to be broken or damaged or deficient in some personal and unfortunate way. Instead, 'disabled' means simply "Not taken into account" (Frazee, 2003). From the beginning, not taken into account in the policies, programs, budgets, laws, curriculum, classroom design, and decisions that structure every conceivable site of human endeavor. Thus the problems faced by disabled people are not merely or predominantly clinical, but problems of living in a social order premised upon the fundamental assumption that everyone who matters engages with the world in standardized, normative manner. Through the emancipatory lens of disability studies, to be disabled is understood as having been marginalized and overlooked, except occasionally, always as an afterthought, and invariably with great fuss (Frazee, 2003).

In this way, disability studies seeks to denaturalize the marginalization of disabled people. It seeks to *depathologize*. Disability is no longer framed as a variant of human functionality but as the outcome of social barriers and deeply entrenched and tacit patterns of discrimination and exclusion (Goodley, 2010). Just as medical framings had always sought – and continue to seek – to eliminate disability through individual cure, rehabilitation or genetic manipulation, the social model seeks to eliminate disability through social change, political reform, and the 'rehabilitation' of community structures and environments (Oliver, 1990; Shakespeare, 2010).

Disability studies sustains these activist beginnings by examining how disability oppression is created. Moreover, disability studies recognizes that disability, impairment, and socioeconomic and cultural influences interact simultaneously to create an experience of disability-in-context rather than an ahistorical static disabled identity. "This framework stands in sharp contrast to the position taken by social work education regarding disability, where the emphasis is on rehabilitation, adaptation, and mitigation" (Hiranandani, 2005: para 11).

The Social Model

The social model of disability challenges the medical model's sole reliance on biology and individual fault. By considering disabled people in context, disability is transformed from one of individual problem to societal discriminations against impaired bodies (biofunctionality of the body). Where the medical model situates disability in the individual's impairment, the social model speaks to societal barriers that disable people from participating in their environments (Barnes and Mercer, 1997). Barriers can include access to buildings, cultural attitudes that presume incapacity for education and employment, and limited transportation and communication tools. In the words of the UK Union of the Physically Impaired Against Segregation (UPIAS), "it is society which disables physically impaired people. Disability is something imposed on top of our impairments by the way we are unnecessarily isolated and excluded from full participation in society" (cited in Thomas, 2004: p. 572). The manner in which social workers intervene in people's lives is dependent therefore on the model upon which they base their practice.

Interventions

Interventions are strategies and processes that change or influence a situation. Disabled people have been the target of a whole range of interventions. These do not have to be negative as some have facilitated full inclusion, community participation, and empowerment. However, others have produced new categories of impairment and disability, created new and demanding standards of normalcy, and have resulted in new forms of social exclusion. Thus interventions can range from the establishment of an independent living center to institutionalization in nursing homes for young disabled people, from a feminist psychotherapy session to pharmaceutical restraints, from a humans rights claim to 'excessive burden' immigration policies. The range of interventions allows each of us – whether we are service providers, advocates, community organizers, family members, or other disabled people – to enter the lives of another, and enact change. The impact of that change, on the other person, ourselves and the world around us depends on the politics informing the intervention. Disabilities Studies is about bringing those politics into the forefront.

What Does a Social Work Practice Not Grounded in a Politicized Disability Activism Look Like?

The following examples are true stories of real people, though each story is a composite of many people's experiences.

Example 1

Aging parents approach a social worker with concerns about their daughter, a young woman labeled with an intellectual disability. They are concerned with their daughters perceived inability to consent to sexual advances and would like to protect her. Typically, this common request has resulted in the disabled person's human rights being violated and the young girl being forced to undergo involuntary sterilization (Diekema, 2003). If the social worker has but one story of disability, it would be difficult for them to critically examine their behavior as one that perpetuates the oppression of the individual. The problem of consent to sexual advances is not solved by sterilization. The young girl may still not be given the opportunity to advocate for herself in situations where sexual advances may occur. The 'problem' that is solved is the one of an unwanted pregnancy, where it is the young girl's parents who do not want the pregnancy. By not examining dominant ideologies about disabled peoples as incapable, social workers can support interventions that perpetuate the exclusion of disabled peoples to participate and make decisions that impact their life.

Example 2

A parent labeled as having a history of depression was told to continue medication and attend therapies approved by the service provider in order to maintain custody of her children. There was no consideration of the repercussion of those medications and therapies. The approved therapy provided by the hospital was almost 2 h away by transit from the person's home and limited their ability to take on full-time work, in effect, disabling them from employment. The assumption is that depression is a medical issue that needs to be fixed. The disabled person must then prove their commitment to be 'not disabled' in order for service providers to allow the disabled person to parent their child. The prevailing notion being that a disabled person cannot be a parent.

Example 3

A mother involved with child welfare was told that in order to have her children returned to her, she had to 'get better.' She was prescribed various medications and told to participate in group therapy sessions. The medications and therapy sessions did little to alleviate her joblessness and poverty. The medications, however, did cause much confusion and sleepiness, disabling the mother from participating in the group therapies in the expected manner. As a result, her behavior was measured as noncompliant. Therefore, within a framework of deficit, that person's disability is most likely scapegoated as the 'problem.' Service providers' unquestioned adherence to a systemic medicalization of disability can also mean that the methods used to 'fix the person' are not questioned, and 'poor recovery' can further mark a person as untreatable, increasing the likelihood of their marginalization.

Example 4

When social workers write reports to child welfare agencies about a parent's abilities to care for a child, that report might be fraught with assumptions about what constitutes a 'good' parent. These do not include parenting as a person with a disability. The intersection of disability and parenting highlights the pervasiveness of a disabled person's body as deficient. When the foundation for service provision is based on ideologies that a person with a disability is not considered competent to provide care, as they are constructed as dependent on

receiving care themselves, it is not surprising that parents with disabilities are more likely to lose custody of their children (National Council on Disability, 2012).

Antioppressive Social Work and Disability Studies

> The philosophy of disability studies and disability rights movements are, in fact, similar to social work principles: all three arenas work for the equal rights, equal opportunities, social justice, self-respect and self-determination. Within a disability rights agenda, solutions to disablement revolve around "self-advocacy, system advocacy, elimination of barriers, and outcomes chosen by the person with disability".
>
> Pfeiffer as quoted in Hiranandani, 2005: para 28

Disability studies and the antioppressive practice (AOP) social work can inform each other in ways that liberate both service providers and service users from the limitations of a single idea of disability. The core of AOP social work practice is to promote social justice by recognizing how power is negotiated between individuals and institutions in ways that benefit some and disadvantage others. Disability studies can give us the tools to recognize and name the implicit bias embedded in our society and institutions that are predicated on racist, sexist, heteronormative, and ableist ideologies (Rushing, 2013). Ableism influences our behaviors in ways that reproduce and legitimize discriminatory practices. As social workers likely employed in institutions that normalize this reproduction of legitimizing discrimination, it is imperative that we implicate our biases and the work we do in potentially contributing to further disablement. Overboe (2007) states that "ableism, like racism and sexism, oppresses people by labeling them as having either a physical, psychiatric, cognitive, developmental, and sensory disability" (p. 23). Social workers must continually question how dominant discourses construct our understanding of disability and impairment.

Antioppressive social work practice highlights the ways in which our biases, if left unexamined, can contribute to silencing the voices of marginalized peoples. Critiques of antioppressive practices challenge the very notion of AOP as an academic and privileged knowledge that does not include the voices and experiences of those most affected by discriminatory practices (Wilson and Beresford, 2000). This makes evident the moral and ethical requirement for AOP social workers to expand our notions of who is an expert. Disability studies recognizes a multitude of voices as experts – specifically those experiences of people labeled and living with disabilities to form the core knowledges of disability. It is this expertise of people's lived experiences of disablement and the unique experiences of the interrelations of peoples many identities that can support social workers to gain new understandings, ultimately encouraging oppressive practices.

Disability studies creates uncomfortable moments as we reflect upon our roles as social workers. Yet it is this very discomfort that can propel us to make change. Social workers need to first examine their own attitudes toward disability and how these biases have determined the way in which they construct or challenge 'a problem.' What do disability and impairment mean to us? What are the implicit biases and/or overt prejudice surrounding disability that impact how we negotiate interventions in people's lives? Do we recognize how disablement interweaves with people's diverse identities to create unique experiences of power and marginalization? Even if no one answer is apparent, the uncertainty that accompanies our self-questioning can support us as social workers to pause, rather than routinely respond to a problem. A politicized understanding of disability can support social workers to explore the possibilities of alternate realities of human differences to liberate ourselves from our 'fear or disability' to work with disabled peoples.

Abstract

The causes and consequences of disability has become an established area of critical geographic inquiry. It emerged in response to changing social conditions (e.g., a vocal disability movement), perspectives on disability (e.g., disability as the outcome of socially constructed barriers to inclusion), and changes in the discipline (e.g., recognition of multiple bases of oppression). The second wave of geographic research on disability has widened the range of differences considered to have disabling consequences (e.g., negotiating places as a 'fat' woman). It has also broadened the range of spaces considered (e.g., to include online communities).

Particularly from the 1990s onward, the sociospatial causes and consequences of disability (i.e., of being socially constructed as negatively different and materially disadvantaged on the basis of mental or physical bodily impairment) has become an established area of critical geographic inquiry. These studies treat disability not as a given consequence of bodily impairment, but as a sociospatial process of marking impaired bodies as negatively 'other' and, on the basis of this negative difference, marginalizing and excluding disabled people from spaces of everyday life. Critical geographies of disability are thus as much about ableism as a regime of power based on able-bodied privilege and the sociospatial practices that sustain it as about disabled persons' experiences of trying to negotiate environments that physically and/or socially exclude and oppress them. While this article focuses on research concerned with disability in the critical social geography tradition, it is important to acknowledge that there have been significant contributions to understanding the geography of disability informed by other traditions of inquiry. Perhaps most noteworthy are Golledge's contributions to understanding visual impairment and wayfinding from a behavioral geography perspective (Golledge, 1993; Loomis et al., 1998).

The development of critical geographies of disability is best understood as a response to both changing conditions within society, and new perspectives on the differences disabilities make in how people are situated (physically, economically, politically, and culturally) within prevailing social relations of power in specific localities, cities, and regions. The former include an increasingly vocal and visible disability rights movement at national and global scales, aging populations with increased vulnerability to and experiences of disability, the restructuring and downsizing of social assistance to vulnerable groups, which has exacerbated and drawn attention to the grinding poverty that disabled people face. New perspectives on disability have also encouraged critical studies of disability and space. The growth of disability studies has drawn attention to a wide range of disability issues, challenged conventional biomedical models of disability with 'social constructionist' alternatives, and offered significant glimpses of what it is like to be disabled in today's societies and spaces of everyday life. Within geography, the growing influence of critical social theory, feminist geographic research highlighting how social differences become bases of spatial and social exclusions, recognition of multiple bases of oppression in society, and concerns to use geographic knowledge as a basis for empowering disadvantaged groups have helped to encourage critical approaches to disability and space.

The sociospatial causes and consequences of disability, that is, of being socially constructed as negatively different on the basis of mental or physical bodily impairment and having to contend with physical and social barriers to inclusion, has become a significant focus of geographic inquiry. Geographers working in this area have helped to demonstrate that scholarly tendencies to assume that only able-bodied women, men, and children occupy and negotiate social space have impoverished our understanding of society and space. Differences in mental and physical abilities affect patterns and degrees of access to urban public spaces, services, and employment opportunities, and help to determine who is most affected by urban and regional changes such as rising poverty and loss of affordable housing. Differences in bodily ability find expression in the geography of cities and regions: in the spatial concentration of disabled persons in poor inner city neighborhoods with a concentration of social services, for instance.

Why a Critical Geography of Disability?

Critical geographies of disability have emerged as a response to changing conditions within society, and new perspectives on the differences disabilities make in how people are situated in society and space (e.g., in terms of access to basic necessities and acceptance in urban spaces). An increasingly vocal disability rights movement, particularly in the West, but also internationally, aging populations with higher incidence of disability, cutbacks in social programs for the disabled, and problems such as grinding poverty and inaccessible cities have helped to encourage such research. New perspectives on disability issues have also been influential. The growth of disability studies has challenged conventional biomedical models of disability with 'social constructionist' ones, and offered significant insights into what it is like to be disabled in various spaces of everyday life (Oliver, 1990; Morris, 1991). These society-centered perspectives view disability as the outcome of social processes such as the economic devaluation of disabled individuals through lack of employment and low wages, and cultural representations of disabled people as inferior. Disability is thus a social rather than individual

condition. This does not necessarily mean that disablement is entirely socially produced. Bodily impairments affect experiences of disablement. Visual impairment may result in difficulty moving within spaces such as sports arenas and negative reactions to such visible differences may help to make disabled persons feel 'out of place.' Similarly, chronic pain sufferers often find it difficult to negotiate spaces of daily life and interact with others. Scholars continue to debate how best to incorporate such bodily realities within conceptualizations of social processes of disablement.

Changes in the discipline have also encouraged critical geographies of disability. These include greater use of critical social theory, feminist geographic studies of a wider range of social differences (e.g., taking sexuality or race into account as well as gender) and how these contribute to marginalization in urban space, recognition of multiple bases of oppression in society and space, and desires to use geographic knowledge to help empower disadvantaged groups. Critical geographers studying disability have promoted related changes in the discipline: such as making conferences more accessible and promoting research through an international network of scholars (i.e., Disability and Geography International). They have challenged the invisibility of disabled women, men, and children in the geographic literature; emphasizing disablement as a sociospatial form of oppression, exclusionary practices within spaces of academia, and the need to put gendered experiences of disability on geography's research map (Chouinard and Grant, 1995).

What do critical geographies of disability offer? They offer the possibility of geographic research that empowers persons with disabilities (building on the legacy of radical geography). They promise more balanced accounts of the sociospatial production of disability as a place-specific condition of life, not a natural outcome of bodily impairment. They can help us understand how ableist social relations and practices are sustained over space and time, and how more enabling environments might be created. They can shed light on why resistance to ableism varies among places of the significance, for example, of national differences in human rights law for disability activism. By providing critical causal explanations of the sociospatial production of disabling environments and of resistance to disablement, these geographies can help us create more enabling societies and spaces.

Research Topics and Directions

It is generally agreed that the first major 'wave' of critical geographic research concerned with disability emerged in the 1990s. Much of this work was captured in Ruth Butler and Hester Parr's (1999) edited collection entitled *Mind and Body Spaces: Geographies of Illness, Impairment and Disability*. Topics covered in this collection included the role of ableist conceptions of the body in architectural discourse and practice (Imrie, 1999), how the onset of physical impairment and heightened sociospatial isolation in the feminized sphere of the home threatens and complicates masculine identities (Valentine, 1999), barriers faced by lesbian, gay, and bisexual disabled people in the gay community (Butler, 1999), and making disabled women's activism and their barriers visible in Canada and beyond (Chouinard, 1999). Among the other noteworthy contributions to a critical geography of disability during this era were Isabel Dyck's (1995) work on the shrinking lifeworlds of women with multiple sclerosis and Brendan Gleeson's (1999) *Geographies of Disability*, a book, which provided a historical materialist analysis that linked changing conditions of disabled people's lives to transformations in production, labor, and ways of life under capitalism. Underlying much of this research was a concern with how and why inequalities of power give rise to social spaces that disadvantage and exclude the disabled persons. This critical stance toward past and present social orders continues to inform more recent critical geographic accounts of disabled people's lives and life spaces, such as Wilton's (2004) analysis of changes in neoliberal state policy in Ontario and how deepening poverty constrains the lives of those with mental ill health. It is, however, perhaps a less singular and unifying concern than in the past.

Since 2000, what is sometimes referred to as a 'second wave' of critical geographies of disability has emerged (Chouinard et al., 2010). This has been characterized, in part, by a more expansive understanding of embodied differences that have 'disabling' consequences, such as Longhurst's (2010) work on experiences of being 'fat' and Holt's (2010) work on how young people with socioemotional differences are (dis)abled within school spaces. It has also been characterized by interest in how embodied differences, such as being chronically ill, alter the meaning of everyday spaces such as the home (Crooks, 2010) and the forging of identities and support in online spaces amongst persons with autism, hearing impairment, and mental ill health (Davidson and Parr, 2010; Skelton and Valentine, 2010). In a related vein, Parr (2008) explores issues of identity, community, citizenship, and inclusion amongst those with mental health differences in rural communities, urban gardens, artistic spaces, and on the Internet. Such work has helped to broaden the range of everyday life spaces considered in geographic research concerned with disability.

Concerns with embodied life, emotions, and experiences of the self-in-place have encouraged some geographers to explore how conditions such as phobia and bipolar disorder alter people's ways of being in and negotiating place (Smith and Davidson, 2006; Chouinard, 2012a). Such work is important in illuminating diversity in embodied life, providing insight into distinctive 'lifeworlds' and support needs, and potentially promoting more inclusive ways of knowing conditions such as 'madness.' Others who share such concerns have explored topics such as how being disabled complicates performances of emotional labor in the workplace (Wilton, 2008). Attention to issues of embodiment, disclosure, and passing is also evident in recent geographic research (Davidson and Henderson, 2010). Critical geographies of care and care giving in relation to groups such as people with developmental differences and the frail elderly are also important in the latest wave of critical geographic research. While interest in this area was apparent in the first wave (Stables and Smith, 1999), this area of inquiry has become more conceptually and substantively sophisticated. So, for example, Milligan (2005) examines emotions involved in informally providing care to the elderly in the home as well as in the transition to

residential care. Metzel (2010) demonstrates the emotional stresses and strains amongst siblings trying to oversee and help provide care to siblings with developmental and intellectual disabilities who live long distances away. She notes the ongoing challenges of trying to monitor the adequacy of care from afar and of managing feelings such as guilt at often not being present in the place where their sibling lives. Power (2010) considers the ways in which contemporary forms of care for persons with developmental disabilities can heighten their dependence and calls for greater recognition of the complex networks of interdependency shaping their lives.

In short, critical geographies of disability, building on the legacies of first wave research, have blossomed into an established, vibrant, and innovative area of inquiry in social geography.

Future Challenges and Directions

Where should geographies of disability go from here? One important challenge, given current emphases on micro- and mesoscale processes of disabled people's embodiment, identity formation, and assignment of meanings to places, is to further advance our understanding of the bigger geographic picture – namely how the uneven development and dynamics of global, neoliberal, and patriarchal capitalism perpetuates social and spatial exclusions of disabled women, men, and children. Systematic studies of how sociospatial restructuring of multilateral and state institutions and programs shape the geographic boundaries and conditions of disabled people's lives in different places would help to address this challenge. Another area for future research is to examine geographic variations in the design, production, availability, and consumption of disability aids, and their impacts on disabled people's abilities to negotiate life spaces. Studies of the sociospatial production of impairment and disabling conditions of life; examining, for instance, how unsafe, stressful conditions of work and the hyperexploitation of female labor in places such as export zones influence the incidence and severity of different disabilities would also help to address this challenge.

A related challenge in advancing our understanding of processes of disablement within the context of a global capitalist order is to, literally and figuratively, push the boundaries of geographies of disability. To date, geographers have overwhelmingly focused their attention on disabled people's lives in affluent nations and have neglected experiences of disability in developing countries of the global South. This is unfortunate given the fact that the vast majority of disabled people live in these countries as it means that geographic knowledge about disability is based on the experiences of a minority of disabled women, men, and children. Chouinard's (2012b) work on disability in the developing nation of Guyana, which places disabled people's material conditions of life and experiences of being disabled in the context of an unequal global capitalist order, is one exception. Dyck (2010), reflecting on new 'body optimization' techniques (e.g., genetic screening) and their implications for geographies of disability, illness, and impairment, points to opportunities for future research to explore issues of power and distributive justice at scales ranging from the personal to the global. So, for example, geographers could explore the power relations and distributive justice issues in the global organ trade. Such work could include addressing the uneven global geography of organ provision and consumption, examining how people are persuaded or coerced to provide organs for sale, and the impacts of organ provision on local communities and on the health of organ providers and consumers.

The second wave of geographies of disability has seen increased attention to cultural practices, images and identities, and their implications for disabled people's lives (e.g., work on how diverse disabled people forge communities and identities through interaction in online space). However, much remains to be done. There is considerable scope for geographers to explore the sociocultural implications of engagement in spaces of artistic endeavor for diverse disabled people. This can include, as Parr's (2008) work with mental health consumers indicates, using artistic projects as a methodological strategy to allow disabled participants to give voice to what they want others to know about their communities, lives, and identities, and to help promote confidence, a sense of being capable and of belonging. Similarly, much of the work remains to be done regarding how popular media, such as commercial films, represent diverse disabled people and the places where they do and do not belong (but see Chouinard's work (2009) on *Girl Interrupted*). Such cultural geographies of disability and the media might include examining how different audiences react to portrayals of disabled people and the places where they belong. Another avenue for research is that of political cultures of place and how these shape disabled people's lives. Are people in urban neighborhoods with a history of disability activism less likely to view disabled people as unproductive citizens who are out of place in local labor markets and communities? Why do activists in some places adopt radical, confrontational strategies demanding collective rights, while others favor actions such as sponsoring stage appearances by famous disabled 'heroes'; events that reinforce cultural notions that only exceptional disabled persons succeed? There is also the challenge, as Kitchin and Wilton (2004) illustrate, of understanding the political and cultural practices and material conditions of activism that allow some disability activists and organizations to 'jump scale' and effect change while others do not.

Theoretical challenges include continuing to develop dynamic, deeply geographic conceptions of the regulation of bodily differences in space; conceptions, that allow for multiple, diverse bases and processes of oppression as disabled women, men, and children move through space and time. Such frameworks could draw, in part, on feminist notions of intersectionality as Valentine (2007) has demonstrated. And they would need to be attentive to the multiscalar nature of these processes – ranging from the intrapersonal scale at which disabled persons grapple with the mental and emotional consequences of marginalization and exclusion through to the global scale where the uneven development of capitalist societies helps to produce oppressive conditions of life for disabled persons.

Methodological challenges include gathering data on neglected aspects of disability such as spatial variations in employment and accommodation practices in workplaces, and developing accessible research formats. Ethical and political

challenges include ensuring that research empowers disabled persons.

Perhaps the key challenge is promoting restless geographic imaginations about disabling environments. Such imaginations will be open to surprise about patterns and processes of disablement over space and time, and willing to learn from disabled people's knowledge. With continued creativity and commitment, future geographies of disability will promote environments that enable all members of society.

Disability Movement

Debbie Jolly, Disabled People against Cuts (DPAC), UK

Abstract

The disability movement is a movement of disabled people for human rights and independent living. Independent living does not mean people doing everything for themselves, but having the support to live in the same way as nondisabled people, with disabled people making their own choices about where and how they live. The article highlights key issues in the independent living movement as well as some of the key players, it ends by focusing on the situation today and why the independent living movement must become stronger in continuing to fight for the human rights of all disabled people.

A Summary of the Beginnings of the Independent Living Movement

The independent living movement philosophy was active in the United States in the 1960s and 1970s with the first well-known Center for Independent Living being established at University of California, Berkeley, in 1972 by Ed Roberts. People in other countries were also active during that time. For example, disabled people in Finland established the first independent living program in 1973, encompassing six Centers for Independent Living (CILs). In 1976, the Union of the Physically Impaired Against Segregation published a manifesto in England in relation to the institutionalization of disabled people and their lack of rights (UPIAS, 1976). This was to be the basis for the social model of disability, a UK model popularized by Finklestein (1980), Oliver (1990), Barnes (1991), and Oliver and Barnes (1998). In the same year, a group of disabled people living in a residential home in Zimbabwe organized themselves for advocacy (Behrent et al., 1999). In 1978, Japanese disabled people organized radical self-advocacy and Switzerland held one of the first conferences of self-help for disabled people (Behrent et al., 1999).

In the early 1980s, the first Canadian CILs were founded, and the first organization of disabled people was created in Nicaragua to provide independent living services and advocacy. In 1981, the British Council of Disabled People was formed (now renamed the UK Disabled People's Council), whilst in Germany a disability rights coalition staged a mock tribunal putting the country on trial for the abuse and segregation of disabled people (Behrent et al., 1999). In the same year, Project '81 initiated the earliest form of direct payments funded by a local authority in the United Kingdom. It enabled disabled people to employ personal assistants (PAs) and was operated by what would later become the Hampshire Center for Independent Living. Campbell and Oliver (1996) note that the disabled peoples' movement in Britain is: "is a movement which incorporates both revolutionary and reformist politics" (p. 179).

CILs and Other Organizations of Disabled People

The independent living movement is a movement of disabled people which campaigns for the full rights of disabled people and is the basis on which all CILs, Centers for Integrated Living, and Centers for Independent Living or CILs have been founded.

CILs are organized and run by disabled people to offer peer support and other services to disabled people. They also engage in work at local, national levels, and sometimes at the European levels to raise awareness and challenge issues that relate to the rights of disabled people.

However, an organization can be about independent living without being called a CIL because what many groups and organizations share is a commitment to the principles of the social model and the aims of independent living. What is important is that they are run and controlled by disabled people. These groups and organizations are called organizations 'of' disabled people in that they have staff, boards, and management committees comprising disabled people. This differs from organizations 'for' disabled people who may not have any or very few disabled staff, with few or none making decisions at board level (Jolly, 2009).

At the same time, organizations 'of' disabled people may not meet the aims of the independent living movement or effectively promote disabled peoples' rights. This occurs when such organizations are merely acting as the passive friend of governments without challenging the barriers disabled people face (Mladenov 2009). It is also unhelpful if organizations work with a charity model that views disabled people as needing 'help' or pity. Such organizations along with many disability charities are likely to promote disabled people lives through a dehumanizing tragedy model of disability to obtain donations for their charities. They effectively take away any responsibility from the state to provide effective policies and disability rights that include disabled people in society. The saying 'Rights not Charity' sums up disabled activists' attitudes to large disability charities who provide residential institutions and are believed to keep disabled people as passive recipients of charity rather than active citizens organizing together for their own rights, self-determination, and further progress for independent living (Jolly, 2009).

The Disability Movement

The disability movement was formed on the premise of independent living for disabled people. Independent living has to do with self-determination and autonomy, the right and

opportunity to engage in life and citizenship as we, as disabled people, chose (The author is a disabled person and identifies politically as a disabled person). Above all, it means the right and duty of the individual to choose, pursue, and manage his or her own way of life. The term 'independent living' is a concept, which underpins the work of disabled people to achieve equal opportunities and full participation in society as equal citizens. The philosophy of independent living argues that disabled people must have equal civil rights and that freedom of choice and the possibility of managing every aspect of life must be ensured. The disability movement represents pan-disability issues. Pan-disability does not refer to single impairment issues, but to disability as social oppression for all people with impairments. Single impairment issues can divide disabled people to the detriment of a movement attempting to gain human rights for all disabled people; inclusivity over such rights is more effective in meeting the aim of independent living and disability rights for all.

It is widely accepted that disabled people have fewer opportunities to participate in the activities of everyday life due to a number of social, environmental, and attitudinal barriers. For example, inaccessible buildings present barriers to participation in leisure and political activities, barriers to inclusive education such as buildings and attitudes prevent education and participation in educational establishments, the same is true of transport and housing: disabled people do not have the same freedom of movement, for example, if public transport is inaccessible, if public housing is not accessible or adapted they have less chances to move from place to place compared to nondisabled people. While some barriers are overt, others can be less so. Instances of these less overt forms can be found in various situations, including within the social fabric of the job interview. For example, in Jolly (2003), Wilde is quoted describing a job interview at a major UK university in which the interview process was described as disabling. Issues included having to walk long distances on a tour of the university, having to wait 6 h for the interview itself as well as a stand-up buffet lunch. When Wilde, who had an invisible impairment was asked why she chose to identify as disabled, it was assumed that this was through an allegiance to disabled people and not because she was disabled herself. Even though she offered to explain this, the interviewers appeared perplexed by her response and terminated the interview. The understanding of disability barriers by this particular university was restricted to physical access needs of wheelchair users. As a result, they were unable to comprehend other barriers to the interview process. The barriers approach is an international one in analyzing societal and attitudinal barriers, which disadvantage disabled people. See Cardona (2013), Shier et al. (2009), Maart et al. (2007), and Moriña Díez (2010) for further examples.

The social model of disability identifies the philosophy and actions that need to be taken to begin to remove the multiple social disadvantages that exist today for disabled people which prevent them from living with the full choices, rights, and control that nondisabled people take for granted. The philosophy of the social model of disability underpins the aims of the independent living movement. The international disability movement lays claim to civil rights and the politicization of disabled people in pursuit of their human rights and full and equal participation (Oliver, 1990; Oliver and Barnes, 2012). This basis of the 'needs to rights agenda' was summed up by disabled people from the Derbyshire Coalition of Disabled People in the United Kingdom.

Seven Needs of Independent Living

The aims of independent living can be succinctly summed up in the seven needs of independent living for disabled people first developed by the Derbyshire Coalition of Disabled People in the United Kingdom in the 1980s.

- Information
- Peer support
- Housing
- Technical aids and equipment
- Personal assistants
- Transport
- Access

While needs and rights may not appear to fit together, the principle is that if certain basic needs are met, this will set the path for better disability rights, because disabled people will be able to fight inequality from a more even playing field of inclusion. The importance of other 'needs' such as education, work, and leisure were recognized, but it was argued that these could be met by mainstream services once the seven primary needs were met (Barnes et al., 1999). In reality, disabled people in many countries are still fighting for these seven needs, as well as inclusive education, mainstream employment opportunities, and access to leisure. This does not mean that there has been no progress, but that progress as a whole differs by country, is variable and affected by different historical and economic circumstance in each country over time.

European Network for Independent Living

In April 1989, the first European Independent Living Conference dedicated to personal assistance was held at the European Parliament in Strasbourg, France. The conference resulted in the founding of the European Network for Independent Living (ENIL). Disabled people from the Netherlands, United Kingdom, Denmark, Italy, Sweden, France, Austria, Finland, Belgium, United States, Hungry, Federal Republic of Germany, and Norway came together at the European Parliament in Strasbourg, France to focus on personal assistant (PA) schemes as an essential factor of independent living with the understanding that independent living encompasses the whole area of activities: housing, transport, access, education, employment, economic security, and political influence. Their statement began: "We, disabled people, recognizing our unique expertise, derived from our experience, must take the initiative in the planning of policies that directly affect us." It went on to condemn segregation and institutionalization, which were described as 'a direct violation of our human rights,' demanding legislation protecting the human rights of disabled people including equal opportunities. Specifically they argued that a key prerequisite to full human and civil rights through independent living is the provision of support for PA services for those that need them. A further prerequisite was that

disabled people should have the opportunity to develop these services for themselves. That is, they should be user led by disabled people themselves.

The participants at this conference called on governments and policy makers to enforce the principles of access to PA services as a human and civil right. Moreover, they demanded that these services would serve all disabled people, of all ages, irrespective of personal wealth, income, or marital and family status. PA services were to be available for anything up to 24 h a day, 7 days a week, for those who required them. Additionally, these were to be paid for from public funds to stop the incarceration of disabled people in closed institutions. A further call was that disabled people and their user-led organizations should be involved in all aspects of policy, planning, implementation, and development. From the initial meeting there has been a mixture of stagnation, progress, and regression on the issues of PA schemes in different countries (Source: http://www.independentliving.org/docs2/enilstrasbourgresolutions.html accessed 20.06.13.).

The International Disability Movement: Some Organizations 'of' Disabled People

Disabled Peoples' International (DPI) (1981–). Disabled people from many groups and organizations around the world attended a conference run by Rehabilitation International – a worldwide organization *for* disabled people (Hurst, 2003). Disabled people were angry that nondisabled people were excluding them from decision making and using their power to retain control over disabled people. The DPI gives disabled people from around the world a chance to share their different experiences of campaigning and to learn from each other. Across the globe, many societies do not take disabled peoples' needs into account, and the DPI realized that because of this, discrimination had to be dealt with at an international level. In 1984, the DPI contributed to persuading the United Nations to change their Declaration of Human Rights to include disabled people (Hurst, 2003; Ratska, 1992).

Disability Awareness in Action (DAA) (1992–2011). Founded by Rachel Hurst OBE, DAA was set up in 1992 as a cooperative project of international disability organizations that responded to disabled peoples' need for appropriate information. DAA's mission was to provide information and evidence to support disabled people in their own actions in securing their rights at all levels: local, national, regional, and international.

Independent Living Institute (ILI) (1989). The ILI is a policy development center based in Stockholm, Sweden. It specializes in consumer-driven policies for disabled peoples' self-determination, self-respect, and dignity (see http://www.independentliving.org/indexen.html accessed 20.06.13.).

The disability movement has been a hive of direct action. This has been direct action in the form of protests, marches, or acts of civil disobedience. These actions have ranged from international actions to country specific actions.

Within different countries, there may be different organizational frameworks, but all their direct actions represent ways of highlighting inequalities in all countries (Shakespeare, 1993). For example, the ENIL has held a Freedom Drive once every 2 years since 2003. This consists of a march to the European Parliament by participating European countries to speak with Members of the European Parliament. In America, Americans Disabled for Accessible Public Transit (ADAPT) have been successfully undertaking nonviolent direct actions on accessible transport in America since 1978. In the United Kingdom, Direct Action Network (DAN) formed in 1993, and organized direct actions especially around transport access.

Also in the United Kingdom, Disabled People against Cuts (DPAC): formed in 2010, was founded and is run by disabled people. It has worked through a series of direct actions including roadblocks, marches, and occupations of government buildings. It also works at the national, international policy and human rights level. In a declassified Government memo, DPAC has been described by the Government's Department of Works and Pensions as 'the most vocal critic' of its austerity policies. Many direct actions at the country level are organized by CILs and other groups that are led and controlled by disabled people. These include among others, CIL-Sofia in Bulgaria, ULOBA or Uavhengig Liv Oslo og omegn (meaning independent life), In and around Oslo in Norway, and YHD (the Association for Theory and Culture of Handicap) in Slovenia. It is clear that with European austerity more radical grass roots groups are being set up to overtake the more formal disability organizations to revive the disability movement in a time of a crisis.

Independent Living Today

The independent living movement today has achieved many changes in the ways that disabled people are treated, including in the physical environment, transport, and access. However, the call for independent living is a call to end the remaining social barriers that prevent disabled peoples' choices, human rights, and inclusion within their own societies, and internationally.

For example, some disabled people seek to employ PAs. PAs can help to negotiate some of the barriers that disabled people face. However, many governments still refuse to fund PAs adequately, or offer only limited financial aid to those seeking to employ them. For example, in the United Kingdom, the proposed closure of the Independent Living Fund for those with perceived complex needs, and the reduction in funds from local authorities through central Government cutbacks has serious implications for the lives of disabled people. Data collected over 2011–12 indicate that social care has already been cut by nearly £4 billion and will be cut by £8 billion by 2015 in the United Kingdom, a cut of about 33% (Duffy 2013). In Sweden, the municipality of Visby limits the tasks PAs can undertake. A person living alone is now expected to live in a flat/house with only two rooms and a kitchen. Those living in a larger flat are told that they should move or pay for the cleaning of the rest of the flat. Members of Parliament reaffirmed the National Social Insurance Office's new interpretation of the limitations on PAs by saying that if you can get the spoon to your mouth or eat by yourself, you do not need PAs, even if you need help in getting the food to the table (Jolly, 2009).

Other governments are also refusing to fund adequately real independent living alternatives. For example, a national

government that declares that they are supporting a PAs scheme, but will only fund an unemployed family member to be the PA, is exploiting family labor by trying to get PAs on the cheap. This stance enables them to remove this person from the unemployment figures and at the same time to pay a low amount of salary to the person for being the PA. This issue has several other problematic respects. One is that self-determination is often better achieved with a PA who is outside the family. Another is that low-cost schemes develop into substandard alternatives to the real goal of independent living, as explained in Panayotova's (2009) *ANED Country Report*.

These responses increase barriers rather than partnering disabled people in the journey toward full citizenship. Many issues remain to be solved effectively. For example, in education, disabled children often find themselves in segregated schools. Housing and transportation can remain inaccessible. And, disabled people are less likely to be employed due to factors such as employers' attitudes, inaccessible workplaces, and lack of aids and support. While many governments proclaim inclusive policies, they do not always implement or enforce those that could improve independent living and citizenship for disabled people. As with the examples on PAs given earlier, many work programs for disabled people can have poor outcomes. A recent program in the United Kingdom was criticized for poor performance by the Public Accounts Select Committee who said "It is shocking that of the 9500 former incapacity benefit claimants referred to providers, only 20 people have been placed in a job that has lasted 3 months, while the poorest performing provider did not manage to place a single person in the under 25 category into a job lasting 6 months" (http://www.publications.parliament.uk/pa/cm201213/cmselect/cmpubacc/936/936.pdf (accessed 20.06.13.)).

These factors are particularly disappointing in light of the United Nations Convention on the Rights of Persons with Disabilities (UNCRPD), which stresses independent living throughout and in Article 19 specifically. The UNCRPD and its optional protocol were adopted on 13 December 2006 at the United Nations Headquarters in New York, and opened for signature on 30 March 2007. A host of countries have ratified the convention and the optional protocol. The signatories and ratifications can be found on the UN website (http://www.un.org/disabilities/countries.asp?id=166 (accessed 09.06.13.)).

It is continued government failures that compel disabled people to continue to work together in organizations 'of' disabled people and grass roots groups to improve disabled peoples' situations and move toward a time when all disabled people everywhere can choose how and where they live as equal members of society.

There is a wide variation in rights achieved in each country, the struggle continues with varying and sometimes lukewarm support by governments. The Academic Network of European Experts in Academia, a project set up in 2007 created and funded under the European Commission's PROGRESS programme, gives a useful, if uncritical, data set of policies for each European country and the European Free Trade Area (EFTA). The purpose of the project is to establish and maintain an academic research network throughout the countries of the European Union and the EFTA to inform disability policy making at the European level. It has a website where such information can be obtained (http://www.disability-europe.net/about-us accessed 09.06.13.). While this is welcome as a resource, true empowerment and equality will be achieved when the European Commission recognizes that it is disabled people themselves who are the experts on their lives, their histories, and the policies that can turn aspirations for change into reality.

Disabled people in every country continue to be more likely to experience poverty. And, gains made in independent living are under attack by austerity measures within many countries experiencing cutbacks. Declining support for disabled people is curtailing their human rights and independent living. Consequently, the gains of the disability movement are being reversed in some countries while remaining static in others. Gaining equal rights and citizenship for disabled people is a battle that will continue.

Abstract

Disability is a universal biopsychosocial phenomenon and involves impairments at the body level, limitations in activity, and restrictions of social participation. Disability is not solely influenced by biomedical pathology but to a large extent by an interaction of environmental factors such as inaccessible buildings or negative attitudes with features of the person such as passive coping styles. Disability is highly prevalent across the world. There is clear evidence for social and psychological determinants as well as consequences of disability.

The Biopsychosocial Model of Disability

The term disability refers to a complex and dynamic interaction of biomedical, psychological, and social factors that become manifest in problems in human functioning and not merely to an attribute that a person has or has not (Bickenbach et al., 1999). Human functioning is an umbrella term introduced by the WHO's International, Classification of Functioning, Disability, and Health (ICF) and reflects the universal human experience in relation to body functions and structures, activities, and participation. Disability, in turn, comprises impairment in body functions or structures, limitation in activity, and restriction of participation experienced by people with a health condition such as a disorder, disease, injury, or trauma (WHO, 2001). Impairments are deviations of physiological and mental functions such as hearing or emotions and/or anatomical parts of the body such as a limb or the brain from statistically defined population norms. Limitations in activities refer to problems people experience in the execution of a task such as lifting an object, and restrictions of participation are defined as problems experienced in relation to involvement in life situations such as pursuing remunerative employment or socializing with friends (WHO, 2001). A person with a health condition may exclusively experience disability in terms of participation restrictions, for example, when a person with HIV is excluded from the labor market. In its current model of disability the WHO (2001) furthermore acknowledges that experiences of disability are influenced by contextual factors, that is, so-called environmental and personal factors. Environmental factors are external features of a persons environment, for example, the accessibility of buildings or attitudes of others. Disability may result from the presence of environmental barriers such as inaccessible buildings or social discrimination or the absence of facilitators such as the lack of supports or assistive technologies. In turn, the presence of facilitators such as assistive devices or social support from family members may reduce disability experience. Personal factors are defined as internal attributes of a person other than impairments or health conditions such as a person's gender, age, education, or coping styles. Personal factors interact with environmental factors in increasing or decreasing disability, for example, in certain cultures females with physical disabilities may be viewed as not eligible for marriage while males do not face similar problems. Against this background, the ICF model of disability (**Figure 1**) integrates two supposedly opposing models of disability, the biomedical or health consequences model which sees disability as a result of disease or disorder and corresponding impairments and the social model of disability which conceptualizes disability as resulting from processes of social discrimination and stigmatization (Bickenbach et al., 1999).

The ICF takes an etiologically neutral standpoint and acknowledges that in some cases disability may result from biomedical factors and in others from social factors or an interaction of both which must be empirically determined (WHO, 2001). Moreover, the ICF conceptualizes disability as a continuum as opposed to a dichotomy, that is, there are various levels of human functioning and disability "and the complete absence of disability, like the complete absence of ability, is a limiting case of theoretic interest only" (Bickenbach et al., 1999: 1182). Furthermore, disability may be a permanent or temporary experience. Therefore, human functioning and disability are universal experiences, that is, every human being has experienced and will experience disability of some sort, in particular with aging (Bickenbach et al., 1999; Zola, 1989).

Prevalence

Estimates of prevalence of disability largely vary between countries if available at all. Prevalence estimates depend on definitions of disability and measures employed, for example, the questions used in a health survey to identify populations with disabilities. In its World Report on Disability published in 2011 the WHO (2011) attempted to provide global estimates of disability prevalence based on the reanalysis of data from two sources: (1) the World Health Survey was carried out between 2002 and 2004 in 70 countries reflecting all regions of the world (for prevalence estimates the WHO selected the 59 countries for which sampling weights were available); data were collected in face-to-face household interviews with person

Figure 1 Integrative model of disability of the International Classification of Functioning, Disability and Health (WHO, 2001).

aged 18 years and older selected based on multistage stratified cluster sampling; the survey included questions on affect, cognition, interpersonal relationships, mobility, pain, sleep and energy, self-care, and vision. (2) The Global Burden of Disease Study integrates data on 130 health conditions from 17 subregions of the world including information on functioning if available; for disability prevalence estimates information collected between 2000 and 2004 was used.

Based on the World Health Survey Data global prevalence of moderate to severe disability was estimated at 15.6% or around 650 million from 4.2 billion people aged 18 years or older in 2004. Extrapolation of data to persons aged 15 years or older led to a prevalence estimate of around 720 million people experiencing disability in 2004. Prevalence was higher in low-resource than high-resource countries, among older people, those with poorer wealth, and females.

Based on the Global Burden of Disease Study disability prevalence was estimated at 15.3% of the total world population including children or around 978 million persons of estimated 6.4 billion in 2004. Prevalence in persons aged 15 years and older was estimated at 19.4% or 892 million.

Extrapolating data to 2010 led to a global disability prevalence estimate of over 1 billion persons including children.

Notably, above figures depend on the thresholds used for determining disability, for example, a threshold of 40 from a total score ranging from 0 indicating no problems in functioning to 100 indicating complete problems for the World Health Survey data. Estimates would be different if another threshold would have been used (WHO, 2011).

Global prevalence of disability is expected to increase in the future due to demographic aging, growing importance of noncommunicable disease, increasing road traffic injuries, and increased occurrence of natural disasters (WHO, 2011).

Classification and Measurement

While health conditions can be classified with WHO's International Classification of Diseases (ICD), functioning and disability as well as environmental factors can be classified with ICF (WHO, 2001). The ICF provides the user with one list of categories for body functions, one list for body structures, one common list for activities and participation, and a list of environmental factors. Currently, a list of categories for classification of personal factors is not included in ICF. All those lists are structured in chapters which include categories of aspects of functioning and subcategories at different levels, for example, Chapter 7 Interpersonal Interactions and Relationships includes a category d720 Complex Personal Interactions which in turn includes subcategories such as d7200 Forming Relationships and d7201 Terminating Relationships. Problems in functioning can be rated with a generic ICF qualifier scale ranging from no problem (0) to complete problem (4). Activities and Participation may be rated in terms of capacity or performance with capacity referring to a standardized environment or test environment and performance referring to a current or actual living environment within which facilitators such as devices or barriers may be present. Difference between capacity and performance thus reflect environmental impact on a person's or population's activity and participation levels. Environmental factors can be rated as barriers ranging from no barrier (0) to complete barrier (4) or facilitators ranging from no facilitator (+0) to complete facilitator (+4). In total, the ICF encompasses 1454 categories making its practical use quite difficult. Therefore, so-called ICF Core Sets have been developed based on literature reviews, expert surveys, patient focus groups, multicenter clinical studies, and international consensus conferences (Cieza et al., 2004). ICF Core Sets provide evidence-based selections of categories that are of major relevance to populations with particular health conditions such as spinal cord injury (Cieza et al., 2010) or to particular settings such as vocational rehabilitation (Escorpizo et al., 2010). Those categories should be considered in clinical practice as well as research. Countless measures of disability or its components are available. The United Nations commissioned Washington Group has developed a short set of seven questions on disability for use in census based on ICF (Washington Group on Disability Statistics, 2010). The WHO-DAS II is a generic ICF-based instrument for self-reported or interviewer-administered assessment of problems in different areas of

functioning (WHO, 2009). Impairments can also be determined with clinical assessment techniques depending on the body function or structure in question. Classical generic measures of limitations in activities of daily living used in rehabilitation include the Functional Independence Measure (FIM) (Keith et al., 1987) and the Barthel Index (Mahoney and Barthel, 1965). Numerous measures of community integration or social participation are also available. The Utrecht Scale for Evaluation of Rehabilitation–Participation (USER-P), for instance, is an ICF-based measure of frequency, perceived restrictions, and satisfaction with participation in different life domains (Post et al., 2012). Different approaches have been used for measuring environmental factors and their impact on functioning (Reinhardt et al., 2011b). People with disabling health conditions may, for instance, be asked to rate certain aspects of their environment as barriers or facilitators or research assistants may observe the presence or absence of several environmental features such as wheelchair accessible toilets or stairs and elevators (Reinhardt et al., 2011b).

Social Determinants and Consequences of Disability

The United Nations (UN) Convention on the Rights of Persons with Disabilities states in its preamble (e) "that disability results from the interaction between persons with impairments and attitudinal and environmental barriers that hinders their full and effective participation in society on an equal basis with others" (UN, 2006) and thus recognizes that determinants as well as consequences of disability may be essentially social in nature. The immediate environment of a person is further to some degree shaped by the organization of society as whole, for example, in terms of legal prescriptions or health policies (Reinhardt et al., 2011b).

Two persons with the same health condition may experience different degrees of impairment and two persons with the same level of impairment may experience different degrees of restrictions in participation depending on the interaction of personal and environmental factors (WHO, 2001, 2011). A study from Switzerland found that impairment was not directly related to restrictions in activity and participation if it was conditioned on contextual factors such as social support (Fellinghauer et al., 2012).

Numerous studies have also demonstrated a social gradient in disability, that is, people with lower socioeconomic status in terms of education and income as well as people with lower levels of social support are at higher risk of developing disability (e.g., Minkler et al., 2006; Reinhardt et al., 2012; Fekete et al., 2014). In the aging population, people with lower socioeconomic status tend to have an earlier onset of disability (Martin et al., 2012). These social gradients vary between countries depending on social and health policies. Wahrendorf et al. (2013), for instance, showed an earlier onset of disability in the aging US population as compared with Europe and that this was mainly due to a larger gap between groups with the lowest and highest wealth. The impact of socioeconomic status on disability may further be mediated by other social factors such as poor working conditions and work stress (Reinhardt et al., 2013).

Disability also may have profound social consequences. People with disabilities have worse educational attainment, are less often employed, and have higher unemployment and poverty rates as compared with the general population in most developed as well as developing countries (OECD, 2010; WHO, 2011). Moreover, persons experiencing profound disabilities are at higher risk of developing secondary health conditions and premature death (WHO, 2011). For instance, a British study of women aged between 64 and 83 found that women experiencing limitations in complex activities and restrictions in participation had an increased risk of mortality (Dale et al., 2012).

The above consequences of disability may be aggravated by other social factors such as inaccessible health care facilities or working environments as well as negative attitudes toward disability in the general population (Reinhardt et al., 2011a) and among health care workers (Tervo et al., 2004). Attitudes toward disability may in turn be influenced by the mass media which have been criticized for a high prevalence of disability stereotypes such as depicting persons with disability as evil (Biklen and Bogdan, 1977). Conversely, positive portrayals of persons with disabilities may improve the general population's attitudes. A study from Switzerland, for instance, demonstrated that attitudes of the general public toward eligibility of persons with spinal cord injuries were improved after watching an action scene showing a wheelchair user in the role of a police detective (Reinhardt et al., 2014).

Personal Factors and Psychological Determinants of Disability

In interaction with environmental factors, personal factors impact disability. As described above, personal factors are not classified in the ICF "because of the large social and cultural variance associated with them" (WHO, 2001: p. 8). In general, personal factors concern the particular background of an individual's life and living and comprise features of the individual that are not part of a health condition or health states (WHO, 2001). Examples of what might be considered as personal factors given are gender, age, coping styles, social background, education, profession, past and current experience, overall behavior pattern, and character (WHO, 2001). This list illustrates some of the difficulties associated with classifying personal factors. Is coping styles different from overall behavior pattern? How can profession be a personal factor if remunerative employment is also a category within the Activities and Participation component? How can current experience be a personal factor influencing functioning? Even an apparently simple variable such as gender leads to discussion, for example, whether to classify biological or social gender. Such difficulties prompted some scholars to question the usefulness of such a classification at all (Simeonsson et al., 2014).

The lack of guidance on how to classify personal factors in the ICF has led to a diverging use of the term personal factors in the literature. In 2011, Geyh et al. reported the use of no less than 238 different personal factors in the literature (Geyh et al., 2011). Several authors have provided proposals for the classifications of personal factors, but there is no glimpse of consensus yet. However, these difficulties also illustrate the need and potential significance of international consensus on

a classification of personal factors for research and health policy.

Broadly spoken, it might be possible to distinguish (1) facts about the individual's position in the physical, social, and temporal context, such as age, gender, ethnicity, partnership, and marriage, from psychological personal factors, within which we might distinguish two subcategories: (2a) the basic psychological makeup of the person, such as personality, optimism, locus of control, and self-efficacy; and (2b) patterns of thoughts and behaviors, such as coping, cognitions about one's condition, and self-management strategies. Research has consistently shown that psychological factors are associated with outcomes such as mood, participation, and well-being in persons with disabilities. Some, such as the personality trait neuroticism, low self-esteem, and passive and avoidance coping strategies with poor outcomes, and others such as extraversion, internal locus of control, and high self-esteem with good outcomes (van Leeuwen et al., 2012).

Psychological Consequences and Adjustment to Disability

After onset of disability, persons are confronted with new situations that challenge their habitual coping strategies, participation, and quality of life. From a health psychology perspective, disability is not unlike any other stressor. The way this stressor is appraised and the effectiveness of the coping response resulting from that appraisal, someone's habitual coping repertoire and other contextual factors determines if the person is able to adjust to the new situation. The term adjustment can be defined as a response to a change in the environment that allows an organism to become more suitably adapted to that change (Sharpe and Curran, 2006). In the context of health, it refers to the healthy rebalancing by patients to their new circumstances. The term adjustment is however used in different ways: (1) to indicate a state of good outcome (de Ridder et al., 2008) and (2) to indicate a process that starts with the onset of disability and continues throughout the course of disability and responds to changes in illness status (Sharpe and Curran, 2006). Most patients experience good adjustment, but for about 30% of patients the adjustment phase is prolonged and sometimes unsuccessful (Taylor and Aspinwall, 1996). Several models have been proposed on how successful adjustment can be achieved (de Ridder et al., 2008). First, the model of cognitive adaptation, which emphasizes illness acceptance and perceptions of control over illness (Taylor, 1983). Second, the personality model that emphasizes the role of factors such as optimism or neuroticism in adjustment. Third, the stress and coping model that emphasizes strategies used by patients to deal with adaptive tasks imposed by disease (Adler and Matthews, 1994). The authoritative stress and coping model acknowledges that chronic illness consists of several challenges, but at the same time, it highlights – more than other models of adjustment – processes of appraisal and coping that explain why some patients successfully identify and act on opportunities to manage these tasks whereas others might fail to do so (de Ridder et al., 2008). More recently, the stress and coping model has been extended with the model of self-regulation, which allows individuals to deal with illness more proactively (Cameron and Leventhal, 2003). Both models show the active role that persons may have in adjusting to the challenges posed by their condition, and they have been used to study processes of adjustment in diverse chronic conditions.

In the self-regulation model (SRM), illness representations contain information about five aspects of the illness: identity, cause, consequences, cure or control, and timeline (Brownlee et al., 2000). Secondly, these representations operate simultaneously at two levels: cognitive and affective. Emotional representations tend to be stronger motivators for behavior than cognitive representations, for example, if one feels bad but avoids a medical consultation because a serious illness might be discovered. According to the SRM, people use knowledge and experience to construct their illness representations. Contextual factors such as social roles and self-perceptions affect these representations (Sharpe and Curran, 2006). The need to develop these representations stem from the need to regulate the self and maintain equilibrium, and to preserve or adapt one's self-perceptions in the light of the new illness (Brownlee et al., 2000).

From this theoretical background it becomes clear why an association is seen between the severity of illness and adjustment outcomes, but why this association is, at best, moderate. A more severe condition has more severe consequences, requires more 'adjustment work,' and results in lower adjustment scores at a given time postonset, but individual differences in psychological makeup and in context cause large variation in the degree to which persons with disability are able to adjust to their situation. For example, a review of studies comparing life satisfaction of people with spinal cord injuries to the general population showed that, on average, life satisfaction scores in samples of persons with spinal cord injury are 0.8 standard deviation below the average scores of the reference populations. Within the spinal cord injury population, however, there was a wide range of life satisfaction and only a weak association between life satisfaction and the degree of impairment or functional limitations (Post and van Leeuwen, 2012).

Abstract

Definitions of disability are socially created and sustained through social interaction and through attitudes of others toward persons with impairments. Major themes in related sociological research include processes of adjusting to disability status, especially socialization and assuming a sick role; understanding disability as a form of deviance; the minority group model of disability; emergence of disability movements; and management of disabling conditions in people's everyday lives. Disability rights policy encompasses multiple agendas, including prevention, civil rights, provision of specialized care, and celebration of disability culture. Global aging and increasing prevalence of chronicity are important reasons to universalize supportive disability policy.

Introduction

Disability can be considered as a limitation in performing socially defined activities and roles to levels that are expected of individuals within a social and physical environment (Pope and Tarlov, 1991). Thus, disability – the expression of a physical or mental limitation in a social context – is socially defined. It can have pervasive social consequences for individuals and for societies. Individuals with widely different types of structural or functional impairments may share common conditions of exclusion, marginalization, and disadvantage. However, shared psychological, social, and economic consequences inherent in the disability experience may be expressed in a strong and positive sense of identity.

The demography and epidemiology of disability vary depending on how persons with disability are defined. In the United States, the Social Security Administration defines persons with disabilities as those who have a physical or mental condition that prevents them from engaging in paid employment. Other definitions of disability include having a condition assumed to be disabling (e.g., deafness); using assistive devices; self-identifying as a person with a disability; and being regarded by others as having a disability. Irving Zola (1993) insightfully argued that the conception, measurement, and counting of disability differ validly depending on the purpose for which this information is needed. In addition, disability is a status that may or may not be applicable at different times in an individual's life. Zola maintained, therefore, that disability is best conceived as fluid and continuous, rather than as fixed or dichotomous. The relevance of the latter point assumes increasing importance in the context of population aging.

After World War II, social scientists working in the fields of social medicine, social policy, and rehabilitation began to focus on social aspects of chronic illness and disability related to injury, but there was little consensus about definitions or approaches to measurement. In 1980, the World Health Organization undertook the development of a supplement to its International Classification of Diseases, which culminated in publication of the *International Classification of Impairments, Disabilities, and Handicaps* or *ICIDH* (WHO, 1980). The ICIDH framework recognized that whether a person performs a socially expected activity depends not simply on the characteristics of the person but also on the larger context of social and physical environments.

With the goals of increasing conceptual clarity and avoiding the suggestion of absolute limitation inherent in the ICIDH use of the term *handicap*, the Institute of Medicine (IOM) offered an alternative conceptual framework that differentiated four related but distinct stages: pathology, impairment, functional limitation, and disability (Pope and Tarlov, 1991). Although progression across these stages might characterize an individual's experience with a chronic disorder, progressively greater loss of function need not occur and the progression can be halted or reversed. Thus, within this framework disability prevention efforts can be directed at any of the three stages that precede disability as well as at the disability stage itself. These efforts could include reversal of disability, restoration of function, or prevention of complications, i.e., secondary conditions, that might exacerbate existing limitations or lead to new ones.

The IOM strongly endorsed a conceptualization of disability that incorporated environmental factors as primary contributors to the creation of disability, and advocated shifting the focus of disability from the individual and the impairment to the interaction between the impairment and the environment. Importantly, in this view the cultural category of disabled was socially, rather than medically, constructed (Higgins, 1992), in part by cultural definitions and in part by the demands and constraints of social and physical environments. This conceptualization challenged the medical model of disability, in which the focus is on an impairment-related limitation in need of remediation.

Sociological research on chronic illness, impairment, and disability originated in an effort to understand the relationship between experiences of symptoms or impairment, the social situations within which people live, and the combined effect these have on people's lives. Major themes that have been developed include adjusting to disability through socialization processes and assumption of a sick role, understanding disability as a form of deviance, the minority group model of disability, emergence of disability movements, and

management of illness and disability in people's everyday lives. Conceptual frameworks applied to the study of disability may embody quite different policy implications.

Processes of Adjusting to Disability

Because the medical model largely equated disability with dependency, much of the early sociological and social psychology research on disability focused on individuals' adjustment to a dependent status. Disability onset was viewed as requiring a redefinition of one's situation and a reconstruction of roles and social interaction patterns (Albrecht, 1976). Scholars focused on adjustment to, and coping with, impairment; morale and motivation in rehabilitation settings; and the importance of social support from family and community. Safilios-Rothschild (1976) noted that there is often a striking similarity in attitudes toward women and persons with a disabling condition and that both were likely to feel a need to accept and adjust to a stereotyped role in order to receive approval. Persons holding multiple roles that are perceived as devalued, e.g., women with a disabling condition, illustrated a situation of double jeopardy (Deegan and Brooks, 1985).

The opportunity for legitimate exemptions from usual role obligations, consistent with assuming the sick role, was regarded by some sociologists as virtually synonymous with disability. Stone (1984) maintained that disability can be viewed as a political privilege in the sense of carrying permission to be exempt from the work-based system, military service, debt, and criminal liability. A sick role perspective in which the interpretation of disability entails exemptions from usual social obligations was seen as characteristic of welfare organizations. Roth (1963) and Blaxter (1976) observed that the way that persons with disabling conditions presented themselves in their help-seeking behavior was shaped by the agencies with which they interacted, setting in motion a continuous process of adjustment. Timetables developed by the medical profession served to structure the patient's 'career' in ways congruent with the agenda of the organization (Roth, 1963), as did stereotypes of the proper client. The more marginal the client, the less precise and valid the stereotype. Societies with more developed formal processes for addressing needs and concerns of persons with disability were more likely to demonstrate tolerance of disability than were societies lacking formal processes, according to Gove (1976).

Conceptualizing Disability as a Form of Deviance

Theories of deviance also had an important influence on sociological studies of disability, beginning with Goffman's (1963) work on spoiled identity and the management of stigma. Safilios-Rothschild (1970) concluded that the position of disabled persons was best analyzed using a general theory of deviance, and early research focusing on persons with blindness considered disability within a deviance or societal reaction theory framework (Scott, 1969). The societal reaction theorist attaches little significance to primary deviance except insofar as others react to it (Gove, 1976). Similarly, Becker (1963) argued that social groups create deviance by making rules where infractions constitute deviant behavior and by applying those rules to particular people and labeling them as outsiders, i.e., offenders. Thus, individuals are processed by government and private agencies and found to be either disabled or not disabled. The disabled might then be channeled into an institutional setting, where there is a disability subculture the person is expected to fit into. Scott (1969) described welfare agencies for the blind as engaged in a socialization process with the purpose of preparing a person with a disabling condition to play a type of deviant role, for example, making blind persons out of people who cannot see.

The literature on disability as deviance argued that, like other stigmatized groups, persons with disability tend to be evaluated as a category rather than as individuals. Two predominantly negative stereotypes are likely to be applied: one stereotype of the particular impairment (blind, deaf, spastic, etc.) and one that is attached to the general label of disabled (Blaxter, 1976). Thus, labeling, segregating, and feedback processes apply to persons with disability as to other deviants. The person with disability is so defined because he deviates from what he himself or others consider normal and appropriate. Individuals may therefore develop a wide variety of concealing techniques in order to avoid the stigmatized label (e.g., Goffman, 1963; Hunt, 1966; Darling, 2013).

Gove (1976) noted that both societal reaction theorists and rehabilitation theorists see disability behavior as largely a product of role relationships. Societal reaction theorists see the social system as creating and stabilizing deviant behavior. Rehabilitation theorists, on the other hand, see the same processes as helping the disabled individual lead a normal life. Whether these social processes are primarily beneficial or detrimental for the individual remains an empirical question.

The greater the individual's resources, the greater the likelihood of avoiding being channeled into impaired or disabled roles. Safilios-Rothschild (1976) noted that high social status is likely to be an overriding characteristic whose desirability can outweigh other characteristics, including disability. Persons considered to have high social status are most likely to be able to retain their majority status rights and to become rehabilitated on their own terms.

The Minority Group Model of Disability

The passage of the Rehabilitation Act of 1973 in the US contributed to a civil rights perspective and, in turn, to a minority perspective in which disability was seen as the product of a disabling environment (Gliedman and Roth, 1980; Stroman, 1982). Within the framework of the minority group model, people are categorized as disabled primarily because of stigmatizing or prejudicial attitudes about discernible bodily differences. The minority group model of disability includes three important postulates:

- the source of major problems for persons with disabilities is social attitudes,
- almost every facet of the environment has been shaped by public policy, and
- in a democratic society, policies reflect pervasive attitudes and values.

Thus, according to the minority group model, both the sources and the solutions for problems of disability are external, and attitudinal discrimination is identified as the major barrier for disabled persons. Moreover, Hahn (1994) argued that disabled persons lack a sense of 'generational continuity', which might enable them to transmit information regarding means of combating prejudice from one cohort to the next. Thus, persons with disability can be termed as an 'unigenerational minority', reacting to perceived social oppression at a particular period.

According to Gill (2001), there are important differences between persons with disability and other minorities, however. One difference noted by Gill is that negative ascriptions based on disability can be linked, at least superficially, to real human differences. Another important difference, she argued, is that unlike members of race and ethnic groups, most persons with disability identify as typical, unless they have developed a political or cultural consciousness that centralizes difference.

Emergence of Disability Movements

In the late 1960s and early 1970s, the civil rights movement, an increasing number of persons with disabilities attending college, and skilled leadership among persons with disabilities provided a combined impetus that contributed to the beginning of the independent living movement (Scotch, 1989). The independent living movement was premised on a sociopolitical model of disability, i.e., disability arising from person–environment interaction as opposed to disability that is linked primarily with the existence of physical or mental impairment. In the US, the independent living and disability rights movements in turn contributed to the framing of the 1973 Rehabilitation Act.

Section 504 of the Rehabilitation Act of 1973 was the first major civil rights legislation for disabled persons in the US, prohibiting discrimination by the federal government and private and governmental entities contracting with the federal government, such as educational institutions. In contrast to earlier legislation that had provided or extended benefits, Section 504 established full participation as a civil right. The legislation represented the convergence of two trends in public policy: (1) extending the nondiscrimination language of the 1964 Civil Rights Act to persons with disabilities and (2) broadening the scope of social programs benefiting disabled persons (Scotch, 2001). The second of these objectives called for increased funding and led to two presidential vetoes of the bill, distracting attention from the first objective of the legislation, i.e., preventing discrimination. A motivating factor for Section 504 was that persons served by the Vocational Rehabilitation (VR) system frequently encountered difficulty entering the job market after completing their training, due to structural and attitudinal barriers. Therefore, without structural modification and protection from discrimination, VR funds were not accomplishing the goal of returning individuals to gainful employment. Section 504 subsequently provided a basis for passage in 1990 of the more comprehensive Americans with Disabilities Act.

In the 1970s, deaf persons protested outside telephone companies around the US because of anger at having to pay for special equipment and the increased costs they incurred for making long-distance telephone calls. This demonstration was interpreted as an emotional response to the shattered hope that years of volunteer effort to achieve telecommunications access would be successful. Exclusion, as in deaf persons' experience of exclusion from telephone access, came to play a positive role in the evolution of a disability community, serving as a catalyst for a sense of shared identity and identifying a target for collective action (Scotch, 2001). In a similar way, black power, feminist, and other social movements of the 1960s stressed a positive self-image rooted in the collective identity of an excluded group demanding greater participation.

Factors that have helped to nurture social movements among persons with disability include:

- medical technologies, including prosthetics, medications, and surgical techniques, that enabled longer life, survival of injuries, and fuller participation in everyday life activities;
- the popularization of an ideology of deinstitutionalization and normalization, especially in the mental health field, that encouraged the growth of noninstitutional support systems and greater participation in community life;
- an increasing number of elderly persons in the society with physical disabilities and shared service needs; and
- a large number of disabled veterans from the Vietnam War who were activists, as well as widespread protests against the war itself that helped to legitimate social activism (Scotch, 2001).

In the US, it was also important that during the 1960s and early 1970s a number of major programs were enacted that promoted more complete participation by persons with disabilities: the Architectural Barriers Act of 1968, expanded funding for vocational and independent living services under the VR program beginning in 1968, the Developmental Disabilities Services and Facilities Construction Act of 1970, the Education for All Handicapped Children Act in 1974, and Project Head Start in 1974. These programs represented a logical extension of a pattern of expanding entitlements and services provided by the federal government based on broadly held social and political values, a pattern referred to by Daniel Bell as a revolution of rising entitlements (Scotch, 2001). This pattern, more than vocal advocacy by disabled persons, is thought to have fostered the adoption of Section 504 of the 1973 Rehabilitation Act in the US Consumer groups did, however, subsequently protest the delayed implementation of Section 504 at offices of the Department of Health, Education, and Welfare, which contributed to disability groups becoming empowered to participate more actively in the political arena.

The problems faced by persons with different types of impairments, and the proposed solutions for these problems, may be quite different, making the development of a shared consciousness problematic (Scotch, 1989). Thus, Barnartt and Scotch (2002) concluded that contentious political actions within disabled communities 1970–99, i.e., demands for desired changes and actions, were typically impairment-specific. Cross-disability protests, involving demands that potentially apply to people with all types of impairments, were found to occur in approximately only one out of four cases. This observation suggested that, because persons with different impairments may lack a shared collective consciousness,

concerted advocacy by large numbers of persons with disabilities is likely to be infrequent.

Managing the Experience of a Chronic Disorder/ Disability

Analyses that attempt to understand how people manage illness in their everyday lives represent an effort to illuminate an 'insider's' perspective. The experience of disability is one focus within the subjective experience of illness, which itself emerged as an interest in part due to the disability movement that had its origins in the 1970s. Self-help and advocacy groups took experiential data seriously, since they were in a sense 'experts' in it, in turn fostering a new social awareness of the problems of living with disability.

A sociology of illness experience is concerned with how people live with and in spite of illness or impairment. It is based on systematically collected and analyzed data from a number and variety of persons with a particular condition, as in Schneider and Conrad's (1983) study of living with epilepsy. The focus is on the meaning of the condition to the individual, the social organization of the individual's world, and the strategies the individual uses in adaptation. Subjective experience provides a window on the broad impact of living with impairment, emphasizing global areas of social life, including work, education, family, sex, identity, and self-esteem.

The experience of disability perspective is qualitatively different from the notion of adjusting to a disability status defined by others, which is an outsider's rather than an insider's view. The experiential perspective recognizes that individuals creatively manage their illness in their everyday lives, defining and redefining who they are and how they relate to others. Corbin and Strauss (1985) argued that illness experience can be usefully conceptualized in terms of work that must be accomplished. Because work is a concept central to the lives of individuals who do not have chronic illness, this conceptualization indicates shared experience for people who are ill and people who are well – an interpretation that differs from the sick role conceptualization. Blaxter's (1976) discussion of the relevance of 'career' for persons with disability who are involved in interactions with social agencies conveys a similar concept. However, the concept of illness trajectory (Corbin and Strauss, 1985) may be even more appropriate for understanding the experience of illness because it encompasses process and change and does not assume linearity or orderliness in progression, such as the concept of career implies. Other focal concerns in research on the experience of illness include the need to manage uncertainty and stigma (e.g., Schneider and Conrad, 1983) and the need for biographical work and reconstitution of self (e.g., Corbin and Strauss, 1985; Charmaz, 1987).

How definitions of disability are socially created or sustained through interaction and through attitudes of others toward persons with disabilities have been a theme in the work of many sociologists. Some researchers suggested that the able-bodied display less variability in verbal output, less smiling behavior, less eye contact, and greater motor inhibition with the disabled. This in turn limits types of social interaction for persons with disability and provides them with fewer opportunities for trying out roles and behavior. The more clearly defined and visible the disability, the greater the ease with which the disabled individual and the group adjust to each other, and vice versa, as shown by Omansky (2011) regarding differing societal responses to degrees of legal blindness. Ambiguity surrounding degree of impairment may negatively impact interpersonal relationships, resulting in confused expectations, goals that are unclear, and roles that are contradictory. Darling (2013) has traced the evolution of disability identity as the construction and experience of difference has changed over time. The underlying theme is that disability is a social status, not a biological condition, and identification – or lack of identification – with the status occurs through social interaction.

New Conceptual Directions within the Sociology of Disability

The growth of the disability rights movement and political efforts to achieve social rights in the 1970s and 1980s were important elements in an emergent change in the conceptualization of disability. The disability rights movement had the goal of changing both the self-concepts of, and societal conceptions about, participants. After the emergence of the disability rights movement, persons with disability were seen as shaping negotiated outcomes ('nothing about us without us'), rather than passively adapting to labels imposed on them. However, disability rights policy encompasses intersecting and competing agendas, including prevention, civil rights, provision of specialized care, and celebration of disability culture, as is well illustrated with respect to policy discussions related to persons with atypical neurological development such as autism (Baker, 2011).

In a sample of disabled activists, Hahn and Belt (2004) found that self-identity related to a personal affirmation of disability was a significant predictor of refusing medical treatment for disabling conditions. Age of onset of the individual's disabling condition was also a predictor. Persons with earlier age of disability onset were more likely to reject curative treatment. Hahn and Belt suggested two potential explanations for the latter finding. First, early disability onset is likely to lead to a stronger personal sense of disability identity. Second, early disability onset gives longer exposure to medical interventions that often prove disappointing because they do not provide cure. In addition to affirmation of disability identity, communal attachments were strong values among the activists who were studied. Ridolfo and Ward (2012) have explored the variety of ways that physical and social barriers shape personal choices about disability identity among people with impaired mobility.

Individuals' desire for connection with others is a recurring theme in the literature on disability, evident in discussions of isolation, invisibility, and struggle (e.g., Zola, 1982). A central feature of the disability insider experience is described as a persistent and disquieting sense of mistaken identity. Tension between the desire to be viewed as 'typical' vs the desire to be able to be comfortable affirming one's personal disability identity (this is who I am) is at the heart of the social experience of disability discussed by Carol Gill (2001). The identity that

the individual struggles to present to the world is commonly dismissed, with stereotypical identity ascriptions substituted for this identity. In one individual's words, 'my disability is how people respond to my disability' (Craig Vick, cited by Gill, 2001: p. 352). Thus, persons with disability critique and continually expand the concept of normality and work to bridge the gap between their self views and public perceptions, and between their inner and outer worlds.

The development of disability movements facilitated acceptance of self, pride, and a focus on positive identity among persons with disability (Hahn and Belt, 2004). At the same time, there is a tension between disability identity and economic and cultural imperatives of a highly normalizing society that pursues the goal of bodily uniformity as measured by criteria such as beauty, health, fitness, and intelligence. An ideology of 'able-ism' has exclusionary social functions, as privileged designations of the body are preserved and validated, providing cultural capital to those who can claim such status. Hahn (1994) argued that the dynamics of capitalism and 'commodity fetishism' encourage people to emulate virtually unattainable physical ideals. The environment, therefore, remains a powerful influence as persons with disability strive for integrity in self and in social relations (Gill, 2001).

Williams (2001) argued that the sociology of disability can benefit from focusing not only on the politics of identity but also on the politics of structures. Developments in social security systems and the entire 'disability business' in Western societies significantly impact the societal meaning of disability (Stone, 1984; Albrecht, 1992). Although a minority group perspective on people with disabilities can have political uses by calling attention to inequities in services and opportunities, it is important to note that Zola (1991) explicitly rejected use of a'us and them' framework. He recognized that aging societies with growing numbers of persons with chronic illness had great significance for the development of the disability movement, creating shared challenges for the able-bodied and the disabled and the opportunity to effectively partner in order to achieve broadly applicable objectives such as available transportation systems and assisted living options.

> Where high economic costs are involved, such as in mass transportation and long-term care, there may well be a decided disadvantage for the needs of people with disabilities to be thought of as 'special' and 'restrictive' rather than general, if not universal.
> (Zola, 1993: p. 30)

Because there are "seemingly infinite permutations of the experience of being physically different in a highly normalizing society", how different impairments translate into complex negotiated aspects of everyday life can be a valuable research focus (Williams, 2001: p.130). There have been few efforts to analyze parallels and differences in the experience and negotiated outcomes of persons with different impairments. Opportunities to develop a shared sense of community is certainly one important variable. For example, having a shared, distinctive language is a very important aspect of membership in the deaf community. The degree to which persons with a particular potentially disabling condition have social contact on a regular basis is another important factor, significantly influencing the opportunity for forming peer relationships. The era of social media provides a new international environment for this contact.

Conclusion

As modern medicine prolongs survival in persons with serious diseases and injuries, an increasing number of persons live longer with a wide range of potentially disabling conditions (Lamas, 2014). Predisease conditions such as obesity are also increasingly recognized as potentially disabling. Overall, there is a progressive shift toward a larger share of the global burden of disease from disability (Murray and Lopez, 2013). The worldwide phenomenon of population aging also has far-reaching implications for the continued development of the sociology of disability. Because every individual will age and is likely to experience one or more physical challenges or chronic illness, accepting the prospect of a disabling condition is the acceptance of an inevitable part of oneself. Changes associated with the aging process thus represent another sense in which normality and disability form a continuum (Blaxter, 1976). As Zola (1989) was early to recognize, population aging, the growing prevalence of chronicity, and the globalization of health risks are important reasons to universalize supportive and equitable disability policy. Disability is socially defined, thus the environment and the expectations for individuals' performance can be redefined, as well as the ways in which individuals with impairments react to the contexts and expectations that they encounter.

Abstract

This article presents key concepts and frameworks that inform disaster management, as well as describes how natural and human-made hazards impact individuals, families, and communities, in diverse ways by considering the local social, economic, and cultural context. Interventions by disaster responders and social workers illustrate the complexities inherent in disaster preparedness, relief, recovery, and mitigation.

Introduction

This article provides a comprehensive overview of 'natural' and 'human-made' disasters, with a discussion of various categories of hazards, as well as the key concepts and frameworks that inform disaster management at local and international levels. Consideration of the underlying social, economic, and cultural contexts and processes that mediate the impact natural hazards and disasters have on certain populations brings forth the needs for human rights, sustainable development, and disaster risk reduction. For many countries, 'natural' and 'human-made' disasters are a relatively common occurrence. The 2004 Indian Ocean and 2011 Japanese tsunamis; earthquakes in China, Haiti, and Japan; flooding in Pakistan, China, and Mozambique; and tropical cyclones in Asia, the Caribbean, the USA, and Central America; along with a continuing series of droughts and epidemics, have affected hundreds of thousands of individuals, families, and communities. Interventions by disaster responders, volunteers, and social workers illustrate the complexities of humanitarian responses.

Natural disasters affect the structures of society by disrupting economic development, increasing income and wealth inequality, marginalizing certain groups, and leading to large-scale migrations (Nel and Righarts, 2008: p. 161). Disaster, social science, and social work researchers are contributing to a growing literature on the relationship between disasters, risk, and vulnerability better to understand the social and economic impacts of disasters, and how natural hazards impact diverse populations between and within societies (Sim et al., 2013; Larson et al., 2013; Mathbor, 2007; Gray et al., 2013; Alston and Whittenbury, 2013; Dominelli, 2012). The terms 'vulnerability,' 'capacity,' and 'resilience' became popular in both the disaster and development literature, and have been applied to policies, with debate and interpretation among various schools of thought (Gaillard, 2010). Available data suggest a pattern of gender differentiation at all levels of the disaster process: exposure to risk, risk perception, preparedness, response, physical impact, psychological impact, and recovery and reconstruction (WHO, 2013). Further, disasters occur each year in locations without sufficient capacity or resources to prevent losses in human life and to support short- and long-term recovery (Alcántara-Ayala, 2002).

Vulnerability

The relationship between hazard and vulnerability has been a concern of disaster practitioners, volunteers, and academics for some time. Hazard refers to the actual physical process involved, while vulnerability is the compounded effect of the exposure and susceptibility of people and their assets to the impact of the hazard, as well as their capacity to anticipate, cope, and recover (Wisner et al., 2003). Ways to minimize risk have been influenced by conceptual frameworks on the unequal distribution of power, resources, wealth, knowledge, and perceptions of risk. The term 'vulnerability' is used to understand how one's status, or social location can influence different impacts of natural hazards. Every individual is influenced by a number of factors that mediate how natural hazards or disasters impact the person: gender, age, physical and mental health status, occupation, marital status, sexuality, race, ethnicity, culture, religion, and immigration status. There are many definitions of vulnerability, which are influenced by social, economic, health, and other perspectives and sectors (O'Brien and Leichenko, 2007; Wisner et al., 2003). Marginalized and vulnerable populations face challenges and struggles in disaster recovery. Older people with fragile health are often weakened when faced with difficult social and environmental changes. People living on fixed or limited incomes may lose important assets, which may lead to destitution. The most socially excluded and economically insecure in any society or community are least able to access or control resources needed before, during, and in the aftermath of a disaster (Larson et al., 2013).

The economic impacts of major 'natural' and 'human-made' disasters are profound for women and men, and gender-differentiated (Alston, 2010; Enarson and Morrow, 1998) as livelihoods, workplaces, and assets are destroyed. The loss of economic resources and deterioration of economic status is most striking on women, who live on the margins of survival, having lived with the 'daily disaster' of poverty before, during, and after natural disasters in many countries (Enarson, 2000). According to the Centre for Research in the Epidemiology of Disasters, since the 1950s, the cost of 'natural' disasters has risen 14-fold. The United Nations estimates that significant economic losses from disaster events around the world now surpass $100 billion each year. Durable and sustained efforts from all actors, such as governments, nongovernmental

organizations and civil society, international agencies and organizations, academic and technical institutions, and the private sector, share responsibility for reducing risks and strengthening resilience.

Capacities refer to the resources and assets that people possess to resist, cope with, and recover from disaster shocks they experience (Davis et al., 2004). Building or enhancing capacities can include activities at the household or community level that strengthen people's strategies or abilities, such as early warning, emergency planning, and preparing resources to cope with disruptions, to face natural hazards.

Building Resiliency

Increased 'natural' and 'human-made' disasters challenge a nation's abilities to mitigate and recover from major events. With the increased frequency, magnitude, and complexity of these events, it is increasingly recognized that prior planning and policies are needed to make communities and populations more resilient to these disruptions. The concept of resilience is currently the subject of research and international debate (Cottrell, 2012; Seville, 2009; Kayser et al., 2008). The Resilience Research Centre (2013) at Dalhousie University defines resilience as "the capacity of people to navigate to the resources they need to overcome challenges, and their capacity to negotiate for these resources so that they are provided in ways that are meaningful."

The *Hyogo Framework for Action 2005–2015: Building the Resilience of Nations and Communities to Disasters* is a 10-year plan endorsed by the United Nations General Assembly in Resolution A/RES/60/195 following the 2005 World Disaster Reduction Conference held in Kobe in Hyogo, Japan. The Hyogo Framework for Action (HFA) aims to substantially reduce disaster loss of lives and social, economic, and environmental assets due to hazards by building the resilience of nations and communities to disasters. The term 'disaster risk reduction' (DRR) refers to the process of understanding, analyzing, and managing the causes and origins of disasters and the risks that grow and lead to disasters. Support for mainstreaming DRR gained momentum in the mid-to-late 1990s, with growing support to integrate disaster risk into development planning and practice. While physical and natural science perspectives contribute knowledge to understanding hazards, there remains an important consideration to understand and reduce human and social vulnerabilities related to disasters. Decision makers and all levels of government, from the international to local municipal levels, face a dilemma in determining priorities for mitigating disaster risks of all kinds. Stakeholders, including policy-makers, have a responsibility to identify and listen to local knowledge when making decisions about disaster risk reduction.

'Natural' Disasters

Many social scientists now reject the popular terminology of 'natural disasters' and stress that while 'hazards' are natural, 'disasters' are not (Horton et al., 2008). A disaster occurs when an extreme event exceeds a community's ability to cope with that event (Lindell and Prater, 2003; Prater et al., 2004; Pyles, 2007). To understand the process by which disasters produce community impacts, it is important to identify the preimpact conditions that make communities vulnerable to disasters. The role of vulnerability as a causal factor in disaster losses tends to be less well understood (Dilley et al., 2005). The destructive power of natural hazards combined with vulnerabilities across various elements can lead to large-scale losses during hazard events in areas where population and economic investment are concentrated (Dilley et al., 2005: p. 23). While losses are experienced at the individual level, in a disaster situation, economic and social systems break down partly or completely, leading to higher socioeconomic impacts.

Climate change is one of the most important environmental concerns of the early twenty-first century with a profound impact on natural hazards. Climate change is caused by natural processes and human activity (IPCC, 2007). Global warming, or increasing average global temperatures, will result in severe consequences for food production, water scarcity, ecosystems, and extreme weather events (McKinnon, 2008). There is a growing literature in social work that considers the role of social workers in climate change adaptation and mitigation (Drolet, 2012; Alston and Whittenbury, 2013; Hetherington and Boddy, 2013; Tester, 2013; Alston, 2010). Natural hazards arise over all time scales, lasting from a few seconds or minutes (earthquakes), to hours (storms), to days (floods), to years or decades (droughts). Different groups have collected data on natural hazards for different purposes. The EM-DAT data set maintained by the Centre for Research on the Epidemiology of Disasters (CRED) in Brussels is the most comprehensive global database on natural hazards and their impacts.

Natural Hazards

This section will consider four categories of natural hazards: (1) hydrometeorological or climatological hazards; (2) geophysical hazards; (3) biological/ecological hazards; and (4) astronomical hazards.

Hydrometeorological or Climatological Hazards

Hydrometeorological or climatological hazards arise from water, weather, and climate. Examples include avalanches, coastal storms, thunderstorms, tornados, floods, droughts, temperature extremes or fluctuations (heat and cold), wildfires, and wind. Severe weather contributes to natural hazards, which can become disasters in many parts of the world.

Hurricane Katrina struck the US Gulf Coast in August 2005, resulting in large-scale destruction due to surge flooding and caused massive overtopping and breaching of levees around New Orleans. Damages to residential property, public structures, and infrastructure and utilities had major economic impacts, along with numerous physical and health impacts. Many of the world's megacities can be found in coastal areas, such as Jakarta, Mumbai, London, and New York. Coastal storms and floods lead to injuries and deaths, with damages to property such as residences, infrastructure, and public facilities, crops, and livestock. Damaged ecosystems disrupt livelihoods and social routines. Community organizing abounds in

postdisaster New Orleans to mobilize on housing issues, neighborhood planning, social and economic development, as well as race and class inequities, to foster social development (Pyles, 2007).

Flooding poses tremendous danger to both people and property. There are several types of flooding: overbank flooding, when the water within a river overflows its banks and spreads across the land around it; flash floods, created by a rapid rise of fast-moving water; ice jam flooding, caused by heavy precipitation pushes ice together and creates a jam; coastal flooding along the edges of oceans driven by storm surges and wave damage; and engineering issues, where a constructed dam gives way, causing a flash flood downstream. The most severe floods occurred in China when the Huang He (Yellow) River exceeded its banks in 1931, contributing to the deaths of 1–4 million people.

Global warming is increasing the frequency and intensity of extreme heat events, or heat waves. Extreme temperatures can have public health consequences and can be life threatening. The 2003 European heat wave led to heat-related illnesses that resulted in many thousands of deaths, of which 14 947 were in Paris, France, alone (Poumadère et al., 2005). Temperatures hovered around 104 °F (40 °C) for seven consecutive days. Many of the victims were older people, who lacked air conditioning and access to coordinated health services, and who were faced with insufficient care during the summer vacation period in August. Environmental experts warn that because of climate change, such heat waves are expected to increase in number in the coming years.

Wildfires are a natural hazard in any forested and grassland region. A wildfire is an unplanned fire in wilderness vegetation or bush, including grass fires and forest fires. The term 'bushfire' is used in Australia, while Canada and the USA refer to 'wildfire.' Devastating forest wildfires are concentrated in summer months when the temperature is high and air humidity and fuel moisture are low. There is a trend toward larger and more intense and damaging fires due to a massive build-up of fuel on the land, declining resources to fight fires, and the loss of traditional fire practices in some countries.

Geophysical Hazards

Geophysical hazards include earthquakes (and associated hazards such as tsunamis and landslides) that are geologically-based, erosion, landslides/rockslides, poisonous gases, sandstorms, soil loss and contamination, and volcanoes. Social workers and social services have significant roles and functions in both rescue and recovery and provide support to vulnerable groups, such as people with disabilities, children, and older people, as well as organize recovery programs that improve the community's ability to address its own unmet needs (Javadian, 2007).

An earthquake is the sudden, rapid shaking of the earth, caused by the breaking and shifting of subterranean rock as it releases strain that has accumulated over a long time. It is estimated that about 5000 earthquakes occur each year. Most of the world's earthquakes take place in the 40 000 km long Pacific seismic belt known as the Pacific Ring of Fire. The greatest risk in an earthquake is the severity of the shaking and ground rupture, resulting in more or less severe damage to man-made buildings and natural structures and the contents within these that may fail or fall and injure or kill people. For example, the 2010 earthquake in Haiti resulted in over 220 000 casualties, and thousands of collapsed structures. Earthquakes that cause the greatest loss of life are deadly because of their close proximity to populated areas or the ocean, where earthquakes often create tsunamis that can devastate communities thousands of kilometers away. Social workers and social services play key roles in earthquake relief by assisting survivors on the frontline of emergency responses (Javadian, 2007).

Tsunamis are long-wavelength, long-period sea waves produced by the sudden or abrupt movement of large volumes of water. A tsunami can travel 600–800 km per hour, depending on water depth. Large waves produced by an earthquake or a submarine landslide can overrun nearby coastal areas in a matter of minutes. Tsunamis can also travel thousands of kilometers across open ocean and wreak destruction on far shores hours after the earthquake that generated them. The 2004 Indian Ocean earthquake was an undersea earthquake that occurred on Sunday, 26 December 2004, off the coast of Sumatra, Indonesia. The earthquake triggered a series of devastating tsunamis along the coasts of most landmasses bordering the Indian Ocean, killing over 230 000 people in 14 countries, and inundating coastal communities with waves up to 30 m (98 ft) high. It was one of the most deadly natural disasters in recorded history and caused serious damage and deaths. The plight of the affected people and communities prompted a worldwide humanitarian response to address short- and long-term recovery. In all, the international community donated more than $14 billion (2004 US$) in humanitarian aid. Social workers have important and unique contributions to make to disaster recovery and reconstruction, research, and ethics through their expertise in ecological approaches, prevention, stress and coping, and promoting transformative change in micro, mezzo and macro systems (Zakour, 1997; Soliman and Rogge, 2002; Javadian, 2007).

Biological or Ecological Hazards

Biological or ecological hazards come from living organisms or ecosystems. Examples include epidemics, microbial pathogens, and poisonous or dangerous plants and animals.

An epidemic may be considered a disaster due to mortality, economic loss, and social disruption, and may contribute to food shortages when disease-affected people cannot work. Human epidemics occur when new cases of a certain disease substantially exceed what is expected in a given human population and during a given time period. Throughout history humans have been affected by epidemics of infectious disease such as the Black Death (bubonic plague) or 1918 flu pandemic. These devastating epidemic diseases affected different population groups in unequal ways due to the unequal distribution of power that produces vulnerabilities that infectious diseases can exploit (Drolet et al., 2013b).

Plant disease, pests, and erosion of biodiversity can affect the variety and variability of animals, plants, and microorganisms. The conservation and sustainable use of biodiversity for food and agriculture play a critical role in human security. Chronic famines have been correlated with the combination of

biological vulnerability and social vulnerability, as evidenced in the Irish Famine of 1845–48 (Ó Grada, 1999).

Astronomical Hazards

Astronomical hazards come from outside the earth, such as asteroids and comets, space weather, and collision or near-collision of celestial bodies with the Earth, and associated hazards (tsunamis, wildfires). The risk from hazards beyond the atmosphere is small compared to other natural hazards. Most asteroids in the solar system come nowhere near the Earth, and smaller ones burn up in the atmosphere. However, in February 2013, a small rock or meteorite disintegrated above the Russian city of Chelyabinsk, injuring about 1500 people. Numerous space hazards are portrayed in Hollywood films, such as 'Armageddon,' 'Impact,' and '2012 Supernova.'

'Man-Made' or 'Human-Made' Disasters

Anthropogenic hazards or human-made hazards can result in the form of a human-made disaster. The term 'anthropogenic' refers to threats with an element of human intent, negligence, or error; it can also involve a failure of a human-made system. A 'human-made' disaster can result in huge loss of life and property and affects a person's mental, physical, and social well-being. Examples include sociological hazards, technological hazards, and transportation events.

Sociological hazards are acts committed against the law and order of the government and can include crime, civil disorder, terrorism, and war. Technological hazards can include industrial hazards, structural collapse, power outage, fire, and hazardous materials. Transportation events can include aviation, rail, road, space, and sea travel.

Human Rights and Disaster

The Universal Declaration of Human Rights (1948) established that all people deserve to live in dignity and with respect. This basic principle is translated into a range of rights articulated by international treaties. For example, the International Covenant on Civil and Political Rights prohibits discrimination on any person because of race, color, sex, language, religion, political or other opinion, national or social origin, property, birth or other status (ICCPR, 1966: Article 26). The United Nations Convention on the Rights of the Child (UNCRC) states that children and youth have the right to freedom of speech and the right to partake in decision-making processes that are relevant to their lives. The 1951 Refugee Convention and 1967 Protocol provide legal protection for refugees with a well-founded fear of being persecuted for reasons of race, religion, nationality, membership of a particular social group, or political opinion (UNHCR, 2001). Human rights relevant to disasters include the right to life, the right to move freely within and between states, freedom of movement, right to housing, and many other interrelated rights, such as the right to health and education. Governments have an obligation to respect, protect, and fulfill rights, even when threats to those rights arise from 'natural' and 'human-made' disasters. Social workers and other professionals play a role in reducing and preventing human rights violations and ensuring that policies and practices promote rights by using advocacy, applying legal standards, and promoting health, education, and social service programing.

Sustainable Development and Disaster Risk

The Brundtland report articulated a commonly accepted definition of sustainable development: "Sustainable development is development that meets the needs of the present without compromising the ability of future generations to meet their own needs" (United Nations, 1987). Social and environmental movements highlight the social justice dimensions of sustainability and the economic, social, and environmental dimensions in light of current inequalities and processes of exclusion.

It is increasingly being recognized that 'natural' and 'human-made' disaster risk must be addressed as a development issue rather than only humanitarian relief assistance, which calls upon governments and other stakeholders to mainstream disaster risk management into development work and activities. The enormous human and economic losses, as well as the costs of relief, rehabilitation, reconstruction, and recovery, make disasters an economic and humanitarian concern. For this reason, disaster risks need to be considered an issue for sustainable development. Social protection initiatives in a number of countries are bringing together humanitarian and development interventions in new ways by addressing vulnerability and risk in short- and long-term approaches through various public actions (Drolet, 2014).

Disaster Preparedness

Early warning principles and systems exist to provide information about a potential disaster to minimize impacts such as fatalities, injuries, damages, and interruptions of normal activities. It is acknowledged that involving communities in people-centered approaches as participants in early warning systems is important. Community members involved in designing warning messages can improve the public's understanding of warning for different target audiences. The United Nations Office for Disaster Risk Reduction (UNISDR) defines preparedness as "the knowledge and capacities developed by government, professional response and recovery organizations, communities and individuals to effectively anticipate, respond to, and recover from, the impacts of likely, imminent or current hazard events or conditions" (UNISDR, 2009). Emergency management aims to manage and control a major emergency in order to reduce the negative impact to life, property, infrastructure, and livelihoods. Stakeholders in emergency response include emergency services, local authorities, public services, nongovernmental organizations, the community, and in some countries, the military and armed forces (Palmore, 2008).

Disaster Relief

The terms 'disaster relief' or 'humanitarian response' cover the immediate response and early recovery. The first and most

important form of relief in the period immediately following a disaster is the provision of basic needs (food, water, clothes, and shelter) to those most seriously impacted. The primary challenge in providing relief is the lack of accurate and reliable information in the early stages. Damage and needs assessments are undertaken in order to provide relief assistance. Social workers design interventions to enhance individual and communal coping skills, stabilize family systems, maximize support, facilitate return to normalcy or 'new normal,' promote and strengthen human rights and social justice, and engage in community development (Kayser et al., 2008; Bourassa, 2009). Social workers identify and address the special needs of vulnerable populations in disaster situations and facilitate emotional expression of grief and loss by listening to survivors' stories, providing psychosocial support, and assisting in finding meaning out of tragedy (Ng, 2012; Bourassa, 2009). Assistance must be offered in a manner consistent with the cultural context in order to support survivors' coping efforts and to build on their strengths and facilitating inclusion of marginalized populations (Kayser et al., 2008; Bourassa, 2009). Social workers build on existing local systems by identifying resources and supports from within the local community. Collaboration with community level workers and volunteers facilitates anti-oppressive and culturally competent services and programs (Bradshaw and Graham, 2007). Recent research on disasters emphasize the significance of social resources in promoting coping and resilience and stress the importance of considering the larger societal context when addressing large-scale disasters. This includes recognition that the individual is embedded in a broader familial, interpersonal, and social context. Social workers are well-situated to develop social interventions to provide individuals, families, and communities with appropriate resources that will support short and long-term adaptation.

Disaster Recovery

For those affected by disasters, following the immediate trauma and shock, the urgent question is how to rebuild lives and livelihood options (Ruwanpura, 2008). Disaster recovery is often handled by a variety of organizations at different levels of government and society, including volunteer groups, national civilian and military agencies, and international relief agencies and nongovernmental organizations. Each brings its own areas of expertise and a number of limitations in terms of jurisdiction and operations. In a large-scale disaster, the recovery process can go beyond the capacity of national governments, and the international community will support recovery by providing aid in cash and kind. The International Federation of Red Cross and Red Crescent Societies (IFRC) is the world's largest humanitarian organization. The IFRC vision is "to inspire, encourage, facilitate and promote at all times all forms of humanitarian activities by National societies, with a view to preventing and alleviating human suffering, and thereby contributing to the maintenance and promotion of human dignity and peace in the world" (IFRC, 2013).

The poor, women, children, older people, and the disabled face more challenges during disasters (Thomas and Twynam, 2006). Social, economic, and political factors determine who lives, works, and has assets in high-risk zones, and shape people's capacities to cope, recover, and adapt. Often women suffer more in disaster events and bear heavier physical and psychological burdens during the recovery period as compared to men. A gender perspective on disasters is necessary to address gender discrimination in everyday life and inequity in times of disasters (Ikeda, 2009; Stehlik et al., 2000). Women face vulnerabilities that result in less economic resources and social protection, which affects their ability to recover from disasters when they occur. Recent research has demonstrated that the inequitable impact of disasters on women is not innate or biological, but socially constructed (Fordham, 2003; Adger and Kelly, 1999). Sexual orientation is another factor in considering gender and disasters; in Indonesia the *warias*, members of the lesbian, gay, bisexual, and transgender community, contributed to disaster risk reduction despite discriminatory practices (Balgos et al., 2012). Old people may be frail and lack mobility, and may also be ill or susceptible to various diseases and conditions before, during, and after disasters (Pekovic et al., 2008). People with disabilities may encounter physical barriers and challenges during evacuations (Christensen et al., 2007). There is a growing body of literature, training tools, manuals, and programs providing information on how to prepare and assist marginalized and vulnerable populations (Tang and Cheung, 2007; Morrow, 1999). The role of social capital, which is defined as a function of trust, social norms, participation, and network, can play an important role in recovery and sustainable disaster mitigation to enhance community preparedness (Ersing and Kost, 2012; Mathbor, 2007; Nakagawa and Shaw, 2004). There is a need to reduce underlying social vulnerabilities through social protection and social policies (Drolet et al., 2013a).

The psychosocial impacts in disaster recovery have emerged as a new area of practice in humanitarian response to address the short and long-term mental health and well-being of affected community members. Many individuals and groups experience stress, and loss and grief, which require needs assessments, support services, and emotional assistance. This can include the psychological needs of disaster workers and emergency responders (Cronin et al., 2007; Smith et al., 2003). The Inter-Agency Standing Committee (IASC) Guidelines on Mental Health and Psychosocial Support in Emergency Settings are used by humanitarian organizations and communities to plan, establish, and coordinate a set of responses to protect and improve people's mental health and psychosocial well-being in emergency situations (IASC, 2007).

Conclusion

There are a number of stakeholders in disaster recovery, including government, academia, communities, business, and civil society. 'Natural' and 'human-made' disasters have impacts on health, food security, and housing and shelter. The quality of the built environment is one of the critical factors that underlie the overall vulnerability of populations exposed to earthquake and tsunami hazards. One of the challenges facing decision-makers and stakeholders is the

recognition of short-term vs. long-term benefits in disaster reconstruction. Media images from recent disasters like the 2004 Indian Ocean tsunami have heightened awareness of natural hazards. The meaning of 'build back better' or 'building back better' is explored in applied research on postdisaster settlement and shelter in terms of involving community, building capacity, and planning ahead for long-term disaster risk reduction (Kennedy et al., 2008). Yet, despite this increased awareness, thousands of lives continue to be lost in subsequent disaster events, and there is more work to be done to mitigate against future events. Local communities offer local knowledge of hazards and can identify their vulnerabilities and needs to strengthen mitigation efforts focused on the natural, built, economic, and social environments. By making connections between the hazard and the vulnerable within local communities, disaster risk reduction is tenable. Disaster preparedness can provide an opportunity to improve safety, enhance equity, and mitigate 'natural' and 'human-made' disasters.

Discipline Formation in the Social Sciences

Abstract

The history of the social science disciplines may be highlighted in terms of four epochal transformations. First, in the late eighteenth and early nineteenth centuries a deep shift occurred from broad genres of discourse on moral and political philosophy into proto-disciplines of a more delimited nature. Inherent in this shift was the constitution of a set of new basic conceptualizations of human agency and human society that came to be of perennial importance. Second, in the late nineteenth and early twentieth centuries a range of inquiries into the social question and into the conditions of institutional and administrative reform were gradually and unevenly transformed into university-based social science disciplines. Third, in the 1920s and 1930s several of these disciplines went through a process of intellectual and institutional consolidation. In this process research programs were formulated that came to serve as focal points for decades to come. Other research programs, often of a transdisciplinary nature, came to occupy a prominent position as intellectual points of reference without finding a secure institutional basis either in an increasingly authoritarian European setting, or in the discipline-based American academic landscape. Fourth, the first three decades of the period after the Second World War were characterized by secular processes, often inspired by American examples, towards disciplinary internationalization as well as professionalization. The social science disciplines also became increasingly subjected to demands to demonstrate their policy-relevance in a broad sense. In the present academic landscape, finally, the social science disciplines are more firmly entrenched institutionally than ever before. At the same time their intellectual and scholarly rationale is being re-examined and there is renewed interest in a dialog about their relationships to each other, to other scholarly and scientific pursuits and to society at large.

Social Science and Disciplinary History

The social nature of human beings means that there have always been rules regulating the life of a community. Tacit social knowledge exists in any human community. The whole of human history is filled with examples of efforts to give guidance to rulers, sometimes written down in books or manuals. Some contemporary social scientists try to trace a lineage of reasoning reaching back hundreds, if not thousands, of years. Thus political scientists often portray Plato and Aristotle as early representatives of their discipline. Economists and educational researchers may point to the perennial nature of the aspects of human life that constitute their scholarly domains. In the case of legal scholarship a tradition, if only in a weak sense of the word, may be said to obtain from at least the twelfth and thirteenth centuries. The emergence of this tradition is in fact coterminous with the creation of European universities (Kelley, 1990). Examples of this kind are interesting in their own right. However none of them amounts to a disciplinary social science history in any real sense of the word. This is so for three reasons (which provide the rationale for the structure of this article).

First, the concept of social science appears only in the 1790s and its use presupposes a meaningful conceptualization of something called a society. This does not occur before the second half of the eighteenth century.

Second, in none of these cases can we talk of a discipline in the sense of a relatively coherent and delimited program of research and teaching that is consolidated and consistently reproduced in a university environment. This presupposes the existence of a university, but also that the university is seen as a primary vehicle for research activities. However, the research-orientated university does not emerge as a key societal institution until the second half of the nineteenth century.

Third, in none of the cases mentioned above is there an unbroken scholarly tradition that links these early efforts to present-day activities in university settings. Such intellectual and institutional continuities presuppose a degree of disciplinary consolidation that does not occur on a more general level until the early twentieth century. In this respect, developments in the 1930s are crucial although limited to Europe and the Americas. Elsewhere, disciplinary consolidation does not occur until after World War II.

The Rise of the Social Sciences: From Moral and Political Philosophy to Social Science

The first recorded uses of 'social science' appear in France in the 1790s. Ever since then, these new forms of knowledge have been characterized by an effort to understand the world of modernity. They have tended to describe key features of this new world in terms of processes of industrialization, urbanization, and political upheaval, originating at the northwestern edge of the Eurasian landmass but eventually having global repercussions. In the self-understanding of the social sciences, accordingly, there is a longstanding and predominant view about the formation of modernity, which highlights transformations in the late eighteenth and early nineteenth centuries. It sees these transformations as a conjunction of a technological and a political transformation – the industrial and the democratic revolutions, respectively. This traditional interpretation, however, radically underestimates the deep-seated epistemic transformation that occurred in the same period.

In fact, in this period there is a fundamental transition from earlier forms of moral and political philosophy into social science. This transition is linked to an institutional restructuring not only in forms of political order but also in the forms in which human knowledge is brought forth and claims to validity are ascertained. One feature of this institutional transition is the emergence of a public sphere that gradually replaces arenas of a more closed nature such as aristocratic literary salons (*see* Civil Society/Public Sphere: History of the Concept). Another is the rise of new or reformed public higher education and research institutions that come to replace both the laboratories of wealthy amateurs and the academies under royal patronage and partial control (*see* Social Science and Universities).

The rise of the social science disciplines must then be cast in terms of the fundamental transformation of European societies that the formation of modernity entailed. One intellectual and cultural transformation in this period pertains precisely to the concepts of society and history and to the new awareness of the structural and constraining nature of societal life. Pierre Manent has put forward the notion that society is a 'postrevolutionary discovery' (Manent, 1998, p. 51). It is true that the term 'society' underwent a long conceptual development in the French context in the course of the seventeenth and eighteenth centuries (see Baker, 1994) – with a dramatic increase in the utilization of the term in the mid-eighteenth century. However, even if there was a long process of gestation for the modern concept of society, the unique event of revolutionary upheaval requires that discursive controversy and political practice become joined in the formation of a distinctly modern era.

The late eighteenth century witnessed the creation of a political project encompassing the whole world and shattering the existing absolutist order. In this process horizons of expectation to use Koselleck's term opened up that were previously unknown. This sense of openness and contingency also served as a forceful impetus to an examination of the structural conditions of the political body and entailed a passage from political and moral philosophy to social science. This transition required that four key problematics – which today are more acutely open to reinterpretation than they have been for decades – be formulated or at least fundamentally reformulated and enter into the new social-science discourse.

First, the role of historical inquiry becomes crucial. Historical reasoning becomes an integral part of the intellectual transition, and even abstract reason itself becomes historicized in early nineteenth-century philosophy. However, the moral and political sciences break up into a variety of new discourses that in the course of the nineteenth century coalesce and are reduced to a number of disciplines. This means that the stage is set for the divergence between a professionalized historical discipline and the other social and human sciences, a divergence that we still today experience as a major intellectual divide.

Second, interest in language and linguistic analysis enters into all domains of the human and social sciences. One outflow of this is the constitution of textual and hermeneutic modes of analysis. There is also an effort to historicize language and linguistic development itself, thereby providing a crucial link with the historic construction of the notion of different peoples.

This leads to a third problematic: that of constituting new collective identities. Membership in a collectivity could no longer be taken for granted in the life experiences of the inhabitants of a certain village or region. Nor could a relationship of obligation and loyalty between the princely ruler and his subjects continue to constitute the unquestionable core of the body politic. That, however, meant that even the most basic categories of societal existence were open to doubt. In the western part of Europe, categories such as 'citizen' and 'compatriot' came to play an even more important role at the turn of the eighteenth century.

Fourth, assumptions about what prompts human beings to act and how to interpret their actions within a broader framework are at the very core of any scholarly program in the social and human sciences. At the turn of the eighteenth and nineteenth centuries, the fundamental categories that we still largely draw upon were elaborated and proposed. We might describe these categories as follows:

a. *Economic-rationalistic*, with a corresponding view of society as a form of compositional collective;
b. *Statistical-inductive*, with a view of society as a systemic aggregate;
c. *Structural-constraining*, with a view of society in terms of an organic totality; and
d. *Linguistic-interpretative*, with a conceptualization of society as an emergent totality.

The transition from a discourse of moral and political philosophy to a social science entailed a decisive shift from an agential – some would say voluntaristic – view of society to one that emphasized structural conditions. In economic theorizing this also entailed a shift away from a concern with moral agency. During the nineteenth century, the context of 'average economic man' became a web of structural properties and dynamic regularities rather than a moral universe of individual action.

Thus, fundamental categories of agency and society that came to be elaborated and refined during much of the rest of the nineteenth and twentieth centuries can be discerned in rudimentary form already during the great transition. So too, however, can some of the features that came to affect these endeavors.

One such tacit but crucial feature concerns the abandonment of the truly universal heritage of the Enlightenment project in favor of forms of representation and endowment of rights based on territoriality or membership in a linguistically and historically constituted and constructed community. Another feature was an emerging and growing chasm between moral discourse and other forms of reasoning about society. Thus, an earlier encompassing conception of the moral and political sciences was gradually replaced by social sciences that marginalized moral reasoning or consigned it to the specialized discipline of philosophy. Third, historical reasoning, which had been at the core of the intellectual transformation at the end of the eighteenth century, became a separate discipline and, toward the end of the nineteenth century, a permanent divide emerged between history and the social sciences.

The end of the eighteenth century was a formative period in the rise of the social sciences in conceptual terms. It is possible to discern, across all confrontations and divergences, a fundamental acknowledgement of the idea that agency, reflexivity, and historical consciousness might help construct a new set of institutions but that this takes place within a complex web of interactions that jointly constitute a society. Thus, there existed a limited number of thematic foci underlying the cultural constitution of a new set of societal macroinstitutions.

The Institutionalization of the Social Sciences: The Social Question, the Research University, and the New Nation-States

Relatively early in the nineteenth century, economics (or rather political economy) became differentiated from moral philosophy. It is also in this period that history emerges as a scholarly field with its own canon of rules, but the full disciplinary formation of history is a highly extended process.

However, social science as an institutionalized scholarly activity performed within a series of disciplines is largely a phenomenon of the late nineteenth and early twentieth centuries. It is an activity that directly and indirectly reflects concerns about the wide-ranging effects of the new industrial and urban civilization that was rapidly changing living and working conditions for ever-larger parts of the population in many European nations during the nineteenth century. These changes, often collectively referred to as 'the social question' (*die soziale Frage*), were gradually forcing themselves upon the agendas of parliamentary bodies, governmental commissions, and private reform-minded and scholarly societies (*see* Social Question: Impact on Social Thought). Often the impetus for the search for new knowledge came from modernizing political and social groupings that favored industrialization but advocated more or less far-reaching social reforms. These groupings gradually came to embrace the notion that political action to alleviate 'the social question' should be based on extensive, systematic, empirical analysis of the underlying social problems. In country after country, the political agenda of the nineteenth century was being formed by two macro-projects: the search for a solution to 'the social question' and to the question of national identity and nationhood within new or reformed nation states (Rueschemeyer and Skocpol, 1996; Wagner et al., 1991a,b).

Between 1870 and the turn of the century, all signs seemed to indicate that new social science approaches would gain access to the scientific institutions. The thinking of their proponents was widely diffused among the intellectual and political elites. This occurred at a time when traditional liberal economics was undergoing a crisis. Thus traditional political economy was seen to be unable to deal with the 'social question' and the widespread deterioration of living and working conditions due to urbanization and industrialization.

However, another important, and indeed competing, field of study and training, whose concerns overlapped those of the new social sciences, was that of the legal sciences. The strength of the legal scholar's position in continental Europe arose from two factors. First, the training function of the universities for the state service produced officials and judges. This meant that legal scholarship came to exert a considerable impact on the general outlook of the servants of the state. Second, legal scholars sought to provide a doctrine, a body of concepts that was based on elaborate technical distinctions and would enable lawyers and judges to act with promptness and precision, clarify the deliberations of the law-maker, and bring coherence and order into the legal system (Dyson, 1980, p. 112). This doctrine was legal positivism, which was first developed for private law and later for public law (in the latter case known as the legal theory of the state). Legal scholarship remained an important alternative to social science and, in fact, strengthened its position towards the end of the nineteenth century. Thus, the so-called 'state sciences' in the German and Nordic states did not really develop into anything that might be labeled 'political science.' Rather they became increasingly embedded in the legal constitutional scholarship that was expanding in Germany in the wake of German political unification. Conversely, in the Nordic countries a similar tradition of 'state sciences' in the late nineteenth century was characterized by a dual legacy of constitutional legal scholarship and, as in Britain, of studies of philosophy and political history.

By and large, approaches to a social and political science did not succeed in institutionalizing themselves in European academia. In some cases, they tried but failed. In other cases, they did not perceive the relevance of academic institutionalization, but blossomed during a passing period of a favorable political climate and decayed with the changing societal situation. For example, the term 'sociology' had been coined early in the nineteenth century, but the key sociologists of the late nineteenth century (Weber, Durkheim, and Pareto) remained broad social science generalists. Their contributions and professional allegiances traversed a range of fields, including politics, economics, education, history and religion, and the term sociology often referred to a broad historical-comparative study of society. However, it was a type of study that saw itself as scientific and separate from reform-orientated activities of a more general nature.

In the United States, social science research originally had the same characteristics of associational organization and ameliorative orientation as in Europe. For example, the American Social Science Association (created in 1865) embraced the notion that the social scientist was a model citizen helping to improve the life of the community, not a professional, disinterested, disciplinary researcher. During the final cades of the nineteenth century, however, this model was gradually replaced by the emerging disciplinary associations such as the American Economic Association (1885), the American Political Science Association (1903), and the American Sociological Society (1905) (Furner, 1975; Haskell, 1977; Manicas, 1987; Ross, 1991). They did not have to face the kind of entrenched opposition or ideologically motivated hostility that many similar efforts in Europe met with (even though it would be misleading to portray these processes as the harmonious unfolding of disciplinary consolidation).

By the turn of the century, a particular pattern of differentiation and professionalization had emerged in the US and proved to be compatible with an active role in government service early on. Economists and psychologists were, for instance, able to play a role in government service as early as World War I, just as demographers were able to do through the Bureau of the Census. At the same time, disciplinary and professional recognition was

being achieved within the setting of American universities which started to become ever more orientated towards research undertakings (Geiger, 1986; Rothblatt and Wittrock, 1993)

This process of successful disciplinary consolidation marked the beginning of a divergence between American and continental European social science. Late nineteenth century American social scientists, many of them German-trained, defined their intellectual projects in a society undergoing a process of rapid transformation: industrialization, urbanization, and concomitantly emerging massive social and political problems. As social scientists with a professional legitimacy, they tried to mark out their own scientific territory and establish their own systems of accreditation. These ambitions entailed the establishment of separate social science disciplines (Manicas, 1987). In Europe, on the other hand, the professorate often already had an established position; one writer (Ringer, 1969) even uses the term 'a Mandarin class' to describe the situation of the leading German academics at the turn of the nineteenth century. The situation in some other countries, such as Sweden and Norway, was no different.

The social sciences emerged as forms of knowledge about societies undergoing fast and deep societal transformations. The relative success of given research programs largely depended on the intellectual coherence and viability of these programs. The cases of Max Weber and Emile Durkheim are exemplary in this respect, but so is the ability of marginalist economics programs to assert themselves even under political conditions which may have appeared as far from advantageous. However, the institutionalization of the social sciences was also clearly related to two other forms of institutional processes.

First, the late nineteenth century was the period when the idea of the university as a key vehicle for research became predominant in a number of countries across the globe, from California in the west to Japan in the east. This process created the possibility for the new social sciences, if in a highly uneven way, to find a relatively stable basis for continued research and training.

Second, the late nineteenth century was also a period of deep institutional change in the political and administrative order in a number of countries. Administrative reforms were undertaken and new objectives assigned to the state. Furthermore demands for wider political representation meant that institutional reforms of the state, not least the demand for a culturally coherent nation-state, created demands upon the social and historical sciences to contribute to these reform processes. The particular forms of interaction between research programs, efforts to deal with the social question, and the relationship of that question to the restructuring of universities and of the state, differed greatly across countries. However, in a number of cases, opportunities arose for the successful institutionalization of some of the social science disciplines in ways that came to structure disciplinary developments in these countries for many decades.

Research Programs in the Interwar World

The end of World War I saw the triumph of liberal democracy and the reorganization of the political order across the European continent as well as a decisive weakening, if not the end, of European global predominance. Soon it became evident that the triumph of democracy was being replaced by its crisis and the emergence of new forms of political and social order with claims to represent the future of humankind in Europe and beyond. It was in this period that pre-eminent representatives of a range of social science disciplines engaged in a self-critical reflection on the history of their own disciplines. Based on such historical reflection, however, they were able to formulate research programs that came to serve as focal points for scholarly endeavors for decades to come.

Within just a few years in the middle of the 1930s a range of pathbreaking programmatic formulations occurred. At this time economists, most notably Keynes in England but also Gunnar Myrdal and the other members of the so-called Stockholm school in Sweden, took stock of the historical experience of their discipline and formulated a coherent long-term research program. In sociology, Parsons' *The Structure of Social Action* was equally historically and programmatically orientated. Its influence extended far beyond the domain of disciplinary sociology and came to affect developments in a number of other fields, including political science and social anthropology. In statistics, Fisher was able to achieve an encompassing synthesis that became a landmark. In political science and sociology, scholars at Chicago and Columbia opened up new areas of empirical research. In Europe, the early work on electoral geography by André Siegfried in France was complemented by sociological and sociopsychological studies by Paul Lazarsfeld and his collaborators in Austria, and by Tingsten's and Wold's minor classic, *The Study of Political Behaviour* (1937).

The comprehensive philosophical programs outlined by the Continental logical empiricists and their Anglo-Saxon counterparts, despite their relative numerical weakness, came to set agendas for years to come. In this respect, Alfred Jules Ayer's polemical and programmatic volume on *Language, Truth and Logic* (1934) became one of the most noted examples, as did Otto Neurath's *Empirische Soziologie* published at roughly the same time. Meanwhile the French Annales School charted a completely new terrain of research that forever changed scholarly efforts in the historical and the social sciences. This was also the period when the first edition of the *International Encylopedia of the Social Sciences* appeared, as a further testimony to need for reflection, for stocktaking but also for the setting of new scholarly agendas.

Furthermore, research programs emerged in the 1930s that positioned themselves in conscious opposition to disciplinary developments in the social sciences and the humanities. One prominent example of this was the broad synthetic program associated with the so-called Frankfurt school. A very different one was the effort of philosophical phenomenologists, most prominently Husserl and Heidegger, to elaborate a conceptualization of human activity from a point of view at odds with that of both analytical philosophy and dominant forms of empirical social research.

Many of these efforts proved to be of lasting importance. However, in institutional terms, the devastating effects of the European political landscape in these years and the ravages of World War II mean that it is difficult to discern clear institutional continuities in the continental European case. Many of the developments in the interwar years were followed by deep ruptures sometimes tended to make the social sciences after World War II appear as a new phenomenon.

The Internationalization of the Social Sciences: The Age of International Associations, Public Policies, and Mass Higher Education

The full-blown institutionalization of the social science disciplines on a global scale is largely a phenomenon of the era after World War II. One manifestation of this was the establishment, originally under the auspices of *UNESCO*, of the *International Political Science Association* (*IPSA*) and the *International Sociological Association* (*ISA*) in 1949. A process of professionalization was set in motion and came to exert a truly profound influence worldwide in the wake of the expansion of higher education systems in a range of countries in the 1960s and early 1970s.

The 1960s saw a dramatic expansion of higher education systems across Western Europe and North America but in many other parts of the world as well. In the same countries, sweeping processes of administrative reform also occurred, which often coincided with the coming to power of new political majorities. Major new public policy programs were launched across the board in these countries. In this context, the social sciences came to be finally and firmly entrenched as academic disciplines in university settings. In this same age of great public policy programs, disciplines such as political science and sociology were able to secure a firm basis in a series of European countries, in some cases for the first time; in others (as in Britain, Germany, Sweden, and Italy) in a renewed and greatly expanded form. This expansion was paralleled by a growth of the social science disciplines on a global level that for the first time tended to make the international associations truly international.

On all continents, the full array of disciplines and subdisciplines appeared. There was also an impressive expansion of research methods being utilized. Thus a previously predominant concern for institutions and processes on a national level was gradually complemented by a stronger research orientation towards the study and management of clearly quantifiable processes. In terms of research methods, the 1960s were the period of the breakthrough of the behavioral revolution; a revolution which had been largely foreshadowed by European scholarly efforts in the interwar period. No longer could historical, juridical, and philosophical reasoning alone or in combination be considered sufficient for the analysis of social and political phenomena. Methods and techniques previously elaborated in statistics, sociology, psychology, and economics were now being tapped by social scientists on a vast scale.

This shift in research methodology coincided with the numerical expansion of the social science disciplines and in Europe was often complemented by the introduction of more formalized graduate education programs, normally with compulsory courses in research methodology. At the same time it became possible to see the emergence of an informal 'invisible college' of younger scholars in Europe and in other continents as well, in marked contrast to the much more national orientation of scholars of older generations. In those universities and countries where this shift was most decisively pushed through, there were certainly instances where the older juridical, historical, and philosophical competence was either partially lost or could at least not be developed on a par with the new approaches. Thus it became gradually antiquated and lost touch with what had been the rationale for the use of these traditional methods in the first place.

Apart from external political-societal reasons for this pattern of disciplinary development, a fundamental fact of a long period after World War II was that only in the United States did the social sciences have sufficient size and scope to make widespread international emulation appear feasible. Thus, for example, the American Political Science Association had more than five thousand members in the early 1950s, when corresponding figures for European nations were generally only on a scale of 1 percent or less of that number. Even in the early 1990s, the combined enrolment of West European political science associations was only a third of that of the American association.

Furthermore, only the American version of a science of society and of politics could present a clear institutional lineage dating back to the late nineteenth and early twentieth centuries. In this perspective, the history of the social sciences in a number of European countries constitutes exceptions to this general tendency only in a weak sense of the word. This is perhaps particularly clear in the case of political science. There has been a persistent notion that political science is intimately linked to the particular intellectual and institutional history of the United States. This can be discerned as early as 1923, in Charles Merriam's presidential address to the American Political Science Association. The same theme recurred 30 years later in the presidential address of Pendelton Herring, and again in the one delivered by Samuel Huntington another quarter of a century later. Political science is then seen to constitute an originally American-conceived science that has successfully spread to a range of nations that (by virtue of their effective, if belated, acceptance of a pluralistic political system) had come to qualify as proper recipients of this intellectual heritage.

Even if such a perspective is understandable, it rests on a misperception. It identifies political science inquiry with one particular form of such inquiry – related to the concerns of liberal individualism. In this and many similar cases, a lack of historical perspective threatens to unduly narrow both the range of problems addressed and the theoretical traditions explored and advanced.

Continuities and Reassessments

Three key features stand out in the development of the social sciences in the late twentieth century. First, their professional consolidation has proceeded. Their institutional position in the modern mass higher education systems seems relatively secure. Never before have there been so many social scientists in the world, and never before have they been so well organized in professional terms, well trained in technical terms, and internationally linked through journals, networks, and research conferences. Many social science disciplines – political science, sociology, educational research, business administration studies, and public policy research – have to a large extent emerged and evolved as confederations of different practices. They have been held together by a common concern with broad substantive themes rather than by a core of theoretical assumptions.

Second, however, it is remarkable to what an extent truly innovative research contributions have resulted from work in scholarly settings outside of the structure of regular disciplinary university departments. Three types of such environments seem to have been particularly important to the intellectual advancement of the social sciences. First, especially in the major American research universities, the system of so-called organized research units has been of great importance in providing settings outside of the departmental structure designed to be hospitable to research of a transdisciplinary nature. Second, research institutes, also normally of a transdisciplinary nature, have been created both outside and inside of the structure of regular universities. In Germany, the institutes of the Max Planck Society have played a crucial role in this respect. Third, the important role of so-called institutes for advanced study has been steadily increasing during the second half of the twentieth century. Such institutes allow scholars, free from the normal concerns of a university department and coming from a variety of disciplines, to focus on their own research efforts during a limited period, normally one academic year. Whereas initially such institutes tended to be international in their scholarly orientation and national in their own organizational structure, there has recently been an increase in the number of such institutes set up within individual universities. The so-called humanities centers now found in a large number of American universities provide one example of this trend. The recommendation of the Gulbenkian Commission (Wallerstein, 1996) that every university create a transdisciplinary institute for advanced study is another indication, a recommendation that now slowly seems to correspond to an emerging institutional reality.

Third, the demands upon the social sciences, from politicians, administrators, and the public at large, to demonstrate the usefulness of their contributions, do not seem to have subsided but if anything to have increased. Sometimes these demands have even resulted in the creation of new proto-disciplines such as social work, criminology, and migration research.

The foremost social scientists of the late nineteenth century had to demonstrate the intellectual and institutional legitimacy of their activities relative to competing forms of scholarship in law, economics, and philosophy. These competitors remain but have been complemented by management consultants, computer experts, and representatives of new transdisciplinary fields such as that of the cognitive sciences.

There is no reason to believe that the social sciences will not be able to defend their current position. It is important, though, to recognize that advances in these sciences depend upon intellectual integrity in the face of an array of demands for immediate usefulness. At the same time, any truly innovative social science inquiry has to be contextually and historically sensitive. This also means that a search for a solution to most of the essential problems of the social sciences has to proceed with a high degree of openness to the contributions from outside of the field of a single discipline. This, however, should be seen as an asset rather than as a liability. In this situation, historical reflection is a necessary component of serious research efforts. Clearly, a number of assumptions concerning our deepest cultural and national identities and their relationship to the basic forms of political and social organization have to be examined anew with the same openness for foundational inquiry as social scientists have shown in earlier periods of fundamental change. In fact, social science scholarship may be crucially important to the possibility of a civilized community of human beings.

Discipline-Building in the Social Sciences: Collective Memory, Biography and Autobiography

Charles Crothers, School of Social Sciences and Public Policy, AUT University, Auckland, New Zealand

Abstract

As they develop, academic disciplines (and their constituent specialties) generate research outputs, theoretical and methodological commentaries, and collective perspectives (particularly disciplinary histories and other collective memories). In addition, there are 'backstories' of how the research outputs are produced from the underlying infrastructure of the discipline and the personal efforts of its members. The production of personal documents (e.g., autobiographies/biographies) is an increasingly important way in which 'the personal' is fruitfully linked up with the 'collective.' But disciplines, while being relatively self-conscious, still lack in collective direction over their operations and trajectories.

Introduction

Academic (science, social science, and also humanities) disciplines, and their constituent specialties, reveal a variety of patterns of change over time. For convenience, the discipline level is assumed in this article but the same points apply to both lower-level entities (e.g., fields or specialties) and to the broader (e.g., social sciences as a whole). A common pattern is for initial discoveries and slow early growth accompanied by some resistance from other specialties, which then escalates into a growth phase in which publications pour out and the intellectual cognitive structure framing these is institutionalized. A final phase can be a slower growth once major innovations in the area have been exhausted, and perhaps a continuing 'after life' in which the reigning intellectual paradigm continues to have some relevance as well as contributing to applications as the cognitive basis for '(social) engineering' interventions. However, along this common path there are many variations (see Abbott, 2001). Alongside the main theoretical and substantive literature in a discipline there also other literature such as that on methodology, which provides guidance about appropriate methods.

There is also a more subjective side of research and publications in which the various disciplines construct socially meaningful cultural frameworks which they then espouse to themselves, their students, scientists in other areas, and the wider community. These can broadly be referred to as 'discipline building.' Such cultural accompaniments construct a possible future and retrieve a plausible past together with providing a 'working model,' providing a shared understanding of how the discipline operates in the present. Such visions indicate what the boundaries of the field are, and in what ways the field differs from any rivals. Such disciplinary cultures also 'localize' a particular version of the overall culture of science and there are also differences in a range of other characteristics, including e.g., preferences between book and journal article publications.

There are two quite separate functions of these articulations of subjective 'disciplinary cultures':

- Assisting in constructing the history or the contemporary culture of the discipline for its own sake and as an ideal held out to motivate adherents and neophytes to the discipline.
- Providing sensitizing methodological reflection which can affect the validity and reliability of the field's findings.

In addition, since research work and writing share some of the commonalities of all social reality, and given the privileged internal access, it can be argued that they can also provide a site for the development of generalized social science knowledge which is just as valid as that obtainable from any other site.

The 'BackStories': Infrastructure and Also Personal Experiences

The scaffolding supporting the work of a discipline often remains in the shadows. The infrastructure of a discipline (its institutions, organizations, funding, techniques, etc.) is a necessary, yet seldom foregrounded, aspect of knowledge production. The ways in which these structures support or hinder research effort is important, but seldom assessed. Moreover, at a personal level the scholars in a discipline each have their own experiences of being involved in knowledge production. And some of these experiences are selectively documented in informal, and sometimes formal ways (e.g., field notes, diaries).

Yet, most of these backstories remain hidden. A sharp line tends to be drawn between the 'public' and the 'private.' More intimate details of the social production of scientific knowledge tend to be suppressed since their exposure might be seen to detract from the ideal of the production of the 'pure truth' that many scientists see as their goal – or as relatively uninteresting. After findings are obtained the 'scaffolding' is disassembled, and even hidden. Public documents tend to produce only the final version of the study and mask the process of attaining this, thus suppressing the "…intuitive leaps, false starts, mistakes, loose ends and happy accidents that actually cluttered up the inquiry" (Merton, 1967, p. 4). Michael Polanyi's concept of 'tacit knowledge' is a more positive version of this idea, which calls attention to the role of unstated (background) knowledge in getting experiments to work.

Academics are motivated by strongly held scholarly norms to keep the public and private spheres of their activities separate and the latter hidden. Moreover, undue attention to the self is seen as self-indulgent. However, a contrasting value motivating

the revelation of backstories can be that of informing and educating the public about academic efforts by allowing them to see the human endeavor required in the production of scholarly knowledge.

Task of Article

In constructing disciplinary collective memories and histories, both objective but also subjective collective and personal sources are drawn upon. Various activities, including developing disciplinary histories, put some of the more private component of knowledge production back out into public view. But accessing the latter requires effort. This article reviews how private but also public 'personal documents' are drawn on in establishing disciplinary histories (of a variety of forms). In particular, there is an interest in understanding whether developing collective memory leads to disciplinary self-consciousness and some ability for its members to guide the future of their discipline.

Unfortunately, there is little systematic work on this whole wider discipline-building area of scientific activity so the references are limited, and mainly found in chapters or journal articles (an interesting exception is Popkin, 2005 on the autobiographies of historians). Much of the literature is reflection (including debate) arising from the publication of particular biographical materials. Studies of discipline building in other than social science disciplines are also pertinent (e.g., Söderqvist, 1996; Shortland and Yeo, 2008).

Disciplinary Collective Memories in Discipline Building

A major component of discipline-building processes is to reflect on and construct that discipline's history and this historical image is usually implicitly built into the discipline's images of its own trajectory (the present and future as well as the past). In more recent decades, efforts have been made to develop contemporary pictures of a discipline, such as by monitoring research outputs and visualizing citation networks or collaboration patterns. Other efforts – such as the famous 'Foresight' programs in several countries – have endeavored to extrapolate or project into the future that topics of scientific knowledge should be focused on. Occasionally, specially constituted commissions to develop research agendas which will guide future research funding and research efforts are appointed. However, largely because many of the necessary facts lie comfortably at hand, construction of backward-looking disciplinary histories is a more usual mode of discipline building.

Apart from textbook coverage and occasional historical tomes, disciplinary historical material can be developed in a variety of ways and on a variety of occasions including particularly presidential addresses, commemorations celebrating turning points (e.g., anniversaries, centenaries). Correspondence between scholars is of major importance as letters (and now e-mails) will reveal much about scholars' concerns, motivations, strategies, and experiences. In turn, the extent to which stock of a scholar's correspondence is kept in some form of archive and then rendered accessible varies enormously. Some correspondence which has survived sits in well-cataloged, well-housed accommodations, whereas others are merely dumped without any finding mechanisms and in premises which are not hospitable to the subsequent researcher who might wish to consult them. And (as Fleck, 2011 points out) for those who fail to be appointed to an official position there is usually not the slightest trace since any records of them are ephemeral.

There is a hierarchy of those who are preferred spokespeople; mainly the discipline's elders and official leaders. After all, they are drawing on experience and the authority of their pronouncements comes from their official or unofficial positions. As a result, it is likely that disciplinary histories will be at least partially shaped by the 'interests' of such spokespeople. For example, to maintain a thoroughly scientific image, some categories of potential contributors to an emergent discipline are 'read out of the picture' – such as those considered not to have made proper scientific contributions or possibly those from less-valued social backgrounds. Resisting this, other historians may endeavor to counter with alternative histories which reinstate such excluded figures and which (often vigorously) outline alternative conceptions of the history of the discipline (e.g., Deegan, 1991). And in turn, more orthodox historians may defend their original configuration (e.g., Hamilton, 2003).

Disciplinary Differences in Disciplinary Histories

The natural sciences are most resistant to revelation of their construction systems because these are seen as almost entirely irrelevant in the advance of scientific activity, and at best tolerated as public relations exercises. At the other pole, the humanities – which are largely concerned with the preservation, articulation, and development of culture – tend to be very historically orientated disciplines. (However, more recently, cultural theory across a range of humanities disciplines has perhaps focused more on structural features without such a concentration on heritage). The social sciences fall in between, with disciplinary histories playing a substantial, but not necessarily major role in their intellectual activities.

The major social sciences disciplines began to become institutionalized from North America and Europe in the 1880s and 1890s – although taking much longer to be properly established in many countries and only becoming common across the world over the last half-century at most. When established they were in the shadow of several centuries of earlier intellectual developments which they had to come to some terms with. And so, there was considerable interest in this prehistory by early writers in each disciplinary area.

Many of the newly forming disciplines developed 'founding myths,' although this varied in importance. Donald Levine proclaimed, for example, that "Sociology was born with a ready-made history" (1995, p. 13) since one of the 'founding fathers' – Comte – included an historical sweep of previous writers in his defining of the discipline he was helping to create (also see, e.g., Helm, 1967).

Some common characteristics shared by disciplinary histories may vary by phase of development, e.g., Merton cites Alfred

N. Whitehead's "it is characteristic of a science in its earlier stages … to be both ambitiously profound in its aims and trivial in its handling of details" (1967, p. 49). Merton argues that grandiose images of the scientific status of a discipline are often produced because of perceived public demand for successful explanatory capabilities. However, the public erroneously judges all disciplines (including the social sciences) in terms of the same standard, ignorant that some disciplines stand at a different phase in terms of development sequences and therefore have more limited current explanatory capacities. Spokespeople for disciplines may need to point out their discipline's limitations to the public.

A common ordering of phases in disciplinary histories involves those of forerunners, founding fathers (few founding mothers tend to be identified), and those responsible for the further development of the discipline. For example, Merton suggested that (1967, p. 2) "…Sociologists retain a most parochial, almost Pickwickian conception of the history of sociological theory as a collection of critical summaries of past theories spiced with short biographies of major theorists" and arranged in chronological order. Often such disciplinary histories are couched as heroic tales, which valorize particular individuals who are thus created as founding fathers or more generally as 'classic' figures.

Not all disciplinary histories tell a simple story of progress. Rather, Levine presents a typology of narratives (1995, pp. 96, 97) which points to a far wider range of alternative images:

- Positivist: history "…does exhibit a progressive refinement of observational and analytical capabilities and a cumulatively developed body of findings";
- Pluralist: "…the universe of viable… approaches consists of an irreducible multiplicity of perspectives, principles, methods, definitions of subject matter, and statements of aims";
- Synthetic: "…agreement has been reached and can be reached on the relevance of certain basic terms, conceptions and generalizations";
- Humanistic: "…that the heritage…contains more than a body of replicable techniques, substantive findings and theoretical analyses";
- Contextualist: that historical contexts have shaped the character of "…concepts and problems in profound, often subtle, ways."
- Dialogical: "…each type arose through critical engagements with the others and …each continues to occupy a place in the broader tapestry." And the trajectory takes the shape of a spiral.

Which trope is used to model the trajectory varies between historians: Levine advocates the dialogical approach which he also claims best represents large portions of sociology's history.

For many social science disciplines, there is a tendency for the systematics of theory and the history of theory to merge and to be conflated when employed in teaching. Theoretical ideas are portrayed as comprising 'packages' which tend to belong to a particular era, although several may be seen as coexisting in the same period. Often such packages are labeled as 'Schools' although these are constructed after the event rather than necessarily being social communities linking a group of colleagues. The history of a discipline is often told as a sequence or series of such 'Schools.' Such idealized disciplinary histories are ideal for more or less simultaneously teaching students the history of the discipline at the same time as the range of theoretical and methodological options available within it.

In his fecund (if problematic) model of scientific developments, Thomas S. Kuhn pointed out the importance of textbooks in indoctrinating new recruits into the mysteries of their discipline and indeed, the packaged histories often included in textbooks can be important for inductees. Although they are not produced to have high standards of historical validity, such versions of history become 'authorized' versions by being produced in textbook accounts.

Levine nicely sums up some more general effects of disciplinary histories (1995, p. 10) "…Collective memories recall great events of the past, which form a focus for group solidarity. They also keep alive the sense of affiliation with the group and its purposes during periods of routine activity between times when the group assembles to reaffirm its collective existence." They can also be defensive, as in remembrance of guilt and difficulty, hopefully overcome by subsequent striving. They can give a sense of duration: extrapolating from past trends or moving forward or backward to some shared history or future history, so they can valorize particular historical directions. They can demarcate boundaries, celebrate the emergence of a new formation or trace its connections/disconnections to others (see also Graham et al., 1983).

Writings from the past of a discipline can also contribute more directly to its present academic work, rather than only its history. Merton has commented on the 'functions' that are served by social science scholars working through earlier material in their discipline (1967, p. 37). Motivations for considering earlier writings

> …range from the direct pleasure of coming upon an aesthetically pleasing and more cogent version of one's own ideas, through the satisfaction of independent confirmation of these ideas by a powerful mind, and the educative function of developing high standards of taste for […] work, to the interactive effect of developing new ideas by turning to older writing within the context of contemporary knowledge.

Merton (1967) has also developed a typology of different ways in which earlier and later work might be related. However, disciplinary histories draw more broadly on the stock of past work than only those elements where there are intellectual connections over time.

Because of the poor quality of many disciplinary histories, there have long been calls for more adequate 'sociological' disciplinary histories in all social science disciplines (e.g., in Sociology, Coser's, 2003 – more sociological treatment of the history of sociology represents an advance over alternative histories which convey less about the social contexts of the writers covered). Merton's sketch of the expertise needed is still pertinent: "…a new breed of specialized historian of science is drawing widely and deeply upon sociology, psychology and tools of science for theoretical guides to their interpretations of

the development of science" (Merton, 1967, p. 3). Better histories

> …would take up such matters as the complex filiation of sociological ideas, the ways in which they developed, the connections of theory with the changing social origins and subsequent social statuses of its exponents, the interaction of theory with the changing social organization of sociology, the diffusion of theory from centers of sociological thought and its modification in the course of diffusion and the ways in which it was influenced by changes in the environing culture and social structure.
>
> Merton, 1967, p. 2

The purpose of these more sophisticated accounts is to achieve better understanding of how things came to be, which is more usually censored from 'Whiggish' disciplinary history accounts which favor a more linear construction of 'disciplinary progress.' So, in the more extended versions of disciplinary histories the material to be included covers

> …conceptions which made good sense at the time of their formulation but were later shattered by compelling empirical tests or replaced by conceptions more adequate to the enlarged facts of the case. It also includes the false starts, the now archaic doctrines and both the fruitless and fruitful errors of the past.
>
> Merton, 1967, p. 3

In constructing more sound disciplinary histories, it is necessary to draw on biographical and other personal documents and experiences.

Personal Documents in Academic Disciplines

This section is organized around asking: who writes what (i.e., content) about whom, where, is published where, and with what effects?

There are several different genres of personal documents:

- Entries in biographical dictionaries
- Obituaries
- Diaries and autobiographical accounts, memoires
- Amateur histories
- 'Sociological' histories
- Professional histories (including those which are theory based)
- Development of more systematic historical studies (e.g., Paul Lazarsfeld's research program on the early development of social research).

This list is organized in terms of a descending continuum of increasing interpretation – those genres listed earlier contain only fairly 'raw' material from a subjective standpoint whereas those listed further down have a higher component of interpretation. Also, validity and reliability of information tends to increase as one goes down the list. However, it is not that simple. Each of the genres has different characteristics, and prescribed lengths of treatment which control the extent of reportage. A major axis lies in terms of the extent of intellectual subject matter versus 'extra-intellectual' coverage of more personal information. Some genres focus almost entirely on subject matter whereas some barely mention this in favor of more extensive biographical coverage. Some genres are particular to some time periods: for example, the biographical eulogies of scholars common in Medieval times.

As well as providing useful descriptive contextualizing, some writing (such as prefaces or introductions) – whether written by the autobiographer/biographer or an editor – can be important in providing a framing for the material: indicating to the reader what sort of lessons they might gain from reading the material and more generally, how to read it. Finally, information about the construction of social science knowledge can contribute to understandings within the sociology of knowledge, such as constructing models of the processes of discipline building.

Development of personal documents (and also collective memories) can include people (social scientists), institutions and organizations or social science 'outputs' (ideas, research), although the first-mentioned predominates. A particular subgenre is sometimes named 'research chronicles' (e.g., Hammond, 1967) or more colloquially 'tales from the field' (e.g., Van Maanen, 2011) as they provide a depiction of the development of a particular research project, which is often collective and relatively short term – in contrast with writing about more individualistic and life-long intellectual careers.

Paradoxically, many personal documents have little personal information, certainly about scholars' private lives. Personal documents tend to suppress awkward, too personally revealing, details. Some are highly formulaic revealing little more than an orthodox 'curriculum vitae.' For example, Fleck (2011) points out that whereas the emigration of the academic social scientist migrants he studied is well documented, their (less renowned) return home is somewhat shrouded in silence. Published biographies may admit to occasional shortcomings but major secrets and deficiencies usually remain hidden. The extent of what is hidden, though, may be disguised by limited revelations of some 'safe secrets.' There clearly is some temptation to present the story of a scholarly life as being more coherent that it really has been, although very often the scholar is represented as being, rather, at the mercy of the fates. Charles Tilly complained that "when forced to confront their own lives, sociology's practitioners … tidy them up, mute their passions, avoid vivisection of their motives, portray themselves as bemused players in a game they do not run, treat their own careers as a series of breaks, lucky or otherwise" (1993, p. 497).

Some personal documents, though, are written in styles which reveal more conflicts, emotions, and struggles. Such accounts to some extent are indeed written to 'pay accounts' and document experienced difficulties. Often such accounts are written by disciplinary outsiders or scholars who came from unusual backgrounds.

Biographical work tends to focus on particular targets, with a strong tendency to concentrate on high-status targets. However, there may be more complex patterns in biographical work: for example, a first generation may be subject to much biographical writing since they are the founders, which may then leave less central precursors, and perhaps the second generation of followers, not adequately treated autobiographically/biographically (see Scarborough and Furumoto, 1989). Biographies also require motivated others to write about the targets, e.g., spouses, disciples, and professional historians.

More detailed kinds of source material include (Merton, 1967, p. 6) scientific notebooks and personal journals and correspondence. The introductions/prefaces in reissued editions of books are frequently informative as they provide an opportunity for the author to review the original circumstances of the book's production and also on how the original work fits in with subsequent developments. Similarly, some authors issue collected volume(s) of their writings which provide opportunities to sketch in the personal strategies lying behind their writing.

Rather than only relying on the somewhat accidental production of public or private documents, more systematic effort can be important. One stimulus is collective biographical exercises where entries are canvassed by an organizer. In many countries, there are state-sponsored national biographies of important people, which very likely will include some social scientists. In particular, there is a need to actively solicit oral histories. Again, systemic programs have occasionally been launched (especially by professional scholarly associations) to endeavor to cover a considerable number of oral histories or indeed more up-market biographical accounts. Surveys of the views, careers, and material circumstances of contemporary social scientists are seldom used, but there are some examples.

Methodology of Constructing Personal Documents: Autobiographies. Coordinated and Collective Autobiographies, etc.

Autobiographies include objective information:

> Like biographers, autobiographers can use personal documents, public documents, the testimony of relevant others and so forth, to compare and contrast these different accounts so that advantages of each is maximized and the disadvantages minimized.
>
> Stanley, 1993, p. 43

Pierre Bourdieu (2008), too, endeavored to avoid his autobiography being seen as falling into a preexisting genre and insisted on it being seen as a 'socio-analysis' of his career – in which social contexts were particularly emphasized. Methodologically, autobiographers stand in a unique relationship to their material. Merton lays out the methodology of autobiography in more detail (see also Oakley, 2010):

> The constructed personal text of the interplay between the active agent and the social structure, the interplay between one's sequences of status-sets and role-sets on the one hand and one's intellectual development on the other, with its succession of theoretical commitments, foci of scientific attention, planned or serendipitous choices of problems and choices of strategic research sites for their investigation. Fully-fledged sociological autobiographers relate their intellectual development both to changing social and cognitive micro-environments close at hand and to the encompassing macro-environments provided by the larger society and culture.
>
> Merton, 1988, pp. 19, 20

Popkin (2001) has particularly commented on the features of 'coordinated biographies' where an array of scholars are invited to contribute to a collection. Appearing in a collected volume can reduce the anxieties of self-indulgence that attends separately published autobiographies. To some extent, a degree of uniformity in style appears, possibly imposed or encouraged by the editor(s). Certainly, in comparison to autobiographical accounts which are pursued at much greater length, there is far less fleshed-out detail.

Collective biographies (prosopography) involve secondary analysis of primary sources of biographical material. The amount of interpretation which can be extracted depends on the quantity/quality of the underlying data sources. Collective biographies allow (once coded) the distillation of patterns (such as careers) and provide some ways of answering questions about how social contexts shape disciplinary developments. Fleck (2011) argues that collective biographies fill a particular gap in the sociological study of disciplines between the units of generations and of institutions and their patterns of changes, i.e., statistics concerning the present versus the long term.

However collective biographies have difficulties, especially, where insufficient data are available; it is best where the group studied is from a common occupational or similar group. Difficulties also arise when different information about a target is yielded from different sources; so rules to adjudicate on conflicting data are needed.

Biographical and other personal document practices in the social sciences follow (and possibly in some parts lead) more general societal developments on such matters. The volume of biographies and the amount of biographical (versus academic) material in them is also affected by academic ideologies.

Already, science biographies have been hailed by some commentators as producing particularly powerful studies, although few social science biographies have yet scaled these heights of acclaim (see also Söderqvist, 1996).

The extent of biographical writings has followed the general 'turn to biography' noticeable from the late 1970s (e.g., Stanley, 1993). Postmodernism as an approach has very strongly emphasized the personal factor, whereas highly positivist endeavors tend to sweep the personal element from the scene although this has not prevented (as in natural science) historical writings.

Particular trends within biographical writing will also affect content, such as the French genre of l'histoire des intelectuels which has been continued over the last century.

> It claims we should know specifically about writers, university lecturers, scientists, journalists of the past: their social origins, their educational background, how much they earned, their clubs, their habits, whom they married (as marriage as a means of social mobility) how their progeny fared, where they lived (rive droite? rive gauche?) where they spent their holidays, whether they were believers or agnostics, monarchists or republicans, pacifists or interventionists, in the resistance or collaborationists and so forth. Their theories insofar as they formulated any are of minor interest for two reasons. The first because they are the subject to other scholars … and second because these theories reflect the context in which they took shape…
>
> Borlandi, 2014, p. 164

Autoethnography takes reflexivity to its ultimate level. Biography is no longer showing how the researcher obtains data from their research site but focuses on the researcher's

personal reactions to the research site – the means has become an end. The researcher becomes his/her research subject. The research site being studied either evaporates or is reduced to somewhat unimportant background.

This approach links to the old standard psychological methodology of 'introspection' (cf Lyons, 1986). While introspection is not a term much valued in contemporary times the method is still widely used in social science, although the terminology has changed and the term repressed – introspection now emerges in the forms of self-report surveys, interviews, etc.

The particular UK research method of 'mass observation' (e.g., Chaney and Pickering, 1986) could be seen as a collective autoethnography since a wide-flung corpus of observers reported on themselves and their immediate social surrounds.

Autobiographical/biographical writing has been encouraged by publishing enterprises such as *Die Wissenschaft der Gegenwart in Selbstdarstellungen* in the 1930s period (Schmidt, 1922) and *A History of Psychology in Autobiography* (American Psychological Association, 1930) from 1930 on. More recently, various *Essais d'ego-histoire* came out in the leading publisher Gallimard's prestigious "Bibliothèque des histoires" series (e.g., Nora, 1987).

The potential for developing more sophisticated disciplinary histories in part relies on vehicles which encourage their publication. One example is the biobibliographical series sponsored by *Greenwood Press* (e.g., Deegan, 1991) which provides reviews of a scholar's oeuvre. Some disciplines have established journal(s) whose focus is the history of that discipline. *Methodologies and Practices*.

The backstory of some research projects has been told and this experience can feed into methodology texts and standards/advice which is toned by the realism of what is possible in the field (see, e.g., Meneley and Young, 2005).

How the scientists interrelate with other 'stakeholders' in their research site will also have major implications for the knowledge which might be drawn, types of access, biases, enforced limitations, etc. Field research is an inherently social process.

Sociobiographical characteristics can have effects on the scientific process.

A full-scale 'social determinism' is unwarranted: social science publications very largely correctly reflect what researchers find. However, biographical data can be drawn upon to reveal some patterns between social characteristics of researchers and their research topics. Biographical material is particularly pertinent in explaining the psychological and social influences on how problems are selected, theories chosen, and particular methodologies pursued.

Some of the links are obvious, although there are more tendencies than determinants: women scholars are more inclined toward research issues involving women, families, and the 'private' rather than the 'public sphere.' Scholars with ethnic or other marked backgrounds are more inclined to study issues relevant to these groups. More generally, there can be a range of ways in which biographical background and experiences affect research. A common pattern is for an academic to be deflected from pursuing another occupation through their scholarly pursuits but to keep up an affinity with the occupation they might have otherwise undertaken a career within. This is particularly evident in applied disciplines where clearly education studies, academics, and classroom teachers share common, overlapping interests and biographies. Linkages to social context can go far deeper. For example, in the process of migrating from Europe to the United States, Fleck argues:

> … the Europeans' focus, methods, and frames of scholarly reference became markedly influenced by American approaches to the social sciences, including adequate external funding, empirical methods, scholarly teamwork, a limited time-frame for projects, and he expansion of the relevant professional disciplines themselves.
>
> 2011, p. XX

Conclusions

The reflexivity brought about through publishing disciplinary histories allows disciplines to reflect and adjust to their circumstances. Experiences are described and their meanings established, and this allows the discipline to attempt to ameliorate difficulties and to take advantage of opportunities. However, disciplinary histories can help to cement in place ossified bodies of knowledge.

Behind these concerns about the social context effect on disciplines lies a theory of the sociology of knowledge, which is that social location (at least partially) together with institutional arrangements (e.g., funding) affects which research problems are addressed and shapes the theoretical and methodological approaches taken.

The organization of the social science disciplines may be consequential for the knowledge produced in them. In the Gulbenkian report, Immanuel Wallerstein et al. (1996) argued that the ossified structure of disciplines reduced the capacity of the social sciences to provide adequate explanations. Social science needs to achieve an appropriate mix between pure and applied work and to be assemble a range of disciplinary/knowledge expertise that covers the full array of phenomena which need to be described and explained. But, there are few mechanisms to ensure that this happens optimally. Hopefully, disciplinary histories, which are in part constructed from personal biographical material, may usefully feed into the needed disciplinary identity and reflexivity that might begin to achieve this.

Discourse and Indentity

Francisco Yus, University of Alicante, Alicante, Spain

Abstract

In this article the relationship between discourse and identity is pictured as an inverted triangle with a broad section at the top for 'inherited' sources of identity (sex, race/ethnicity, nationality) that have discursive correlates. The section in the middle represents 'optional' social groups to which the individual chooses to belong (and which often involve jargons that create barriers of discursive specificity). Finally, the bottom vortex of the triangle represents the individual as a specific holder of identity, discursively exhibited as the person's idiolect. Furthermore, in this article it is argued that the Internet alters this triangle by re-inverting it and that it also influences the extent and scope of some traditional discursive sources of identity.

The human being is inextricably tied to language. As soon as children are born, a biologically rooted, built-in discourse-developing mechanism is activated enabling them to become communicatively competent, to interact with the world, and to become aware of their role and specificity in society. However, not all discursive sources of identity have the same quality and strength. In Yus (2001), three major discursive sources of identity were schematized as an inverted triangle in which the broad section at the top represented 'inherited' sources such as nationality, sex, and race/ethnicity. A narrower section in the middle of the triangle represented 'optional' identity sources, mainly social groups to which the human being chooses to belong (often with group-specific jargons). And finally, a very narrow section at the bottom of the inverted triangle represented the human self as it is developed and shaped through everyday face-to-face conversations. These layers are still valid today. However, in that article a fourth section was suggested that deals with contemporary communication through the Internet, which actually *inverts the inverted triangle*, providing surprising options for identity shaping. Nowadays, on the contrary, since we no longer log onto the Net but mostly live inside it, Internet sources of identity now tend to mesh and imbricate with offline counterparts, making it difficult to address discourse and identity as represented by two non-touching triangles.

'Inherited' Sources of Identity

When a child is born, it inherits several distinctive discursive features such as belonging to a community (e.g., a nation), being male or female, and having distinctive racial or ethnic features. All of these inherited qualities have closely related discursive features (consolidated as the child grows up) ranging from living in a speech community (any human collectivity characterized by regular and frequent interactions through language) to particular sex- or race-related features.

The role which discourse plays in the community (i.e., the nation in a broad sense) as a source of identity varies depending on its current sociopolitical state, but in all cases it is one of the clearest sources of social identification: "Groups of people who occupy contiguous territory and see themselves as having common interests tend to develop, over long stretches of time, ways of speaking that are distinctive to them, marking them out from groups who either are not geographically adjacent to them or else are perceived as having different, probably rival, interests" (Joseph, 2006). This level of identity relates to Turner's (1987, p. 45) intermediate level of *ingroup–outgroup categorizations* between the broad superordinate level of being human and the subordinate level of *personal attributes*.

Needless to say, the sense of belonging to a community and sharing the same language, a major source of identity, goes beyond the political lines as drawn on maps. This is why the speech community, defined as "any human aggregate characterized by regular and frequent interaction by means of a shared body of verbal signs and set off from similar aggregates by significant differences in language use" (Gumperz, 1971, p. 114) is a much better term, since it goes beyond the reductionist view of society as a clear-cut physical space with members speaking the very same language, even if the notion of 'place' has traditionally been regarded essential to foster feelings of community membership (Walker, 2007).

On the other hand, places in which a shared language is embraced as part of a broader resistance against other imposed languages, as is the case of Quebec in Canada or Catalonia in Spain, tend to originate very tight links between discourse and identity, whereas in more politically stable linguistic areas this source of identity may not be felt so explicitly.

Another major identity marker is sex. There is now a huge amount of bibliography dealing with (non)-verbal speech differences of men and women in same-sex and cross-sex conversational interactions. To a certain extent, fitting the expected discursive attributes of one's sex may reinforce personal identity as a sense of *belonging to a social group*. General areas of research include vocabulary differences (including the traditional coining of male-connoted words) and the analysis of conversational *genderlects* (systems of linguistic features linked to one of the sexes).

Finally, the relationship between race, discourse, and identity is important since one's race may be a strong link to society as a multifaceted experience covering such aspects as the recognition of biological origins and, on some occasions, also a deep reinforcement of personality against oppressive, racist attitudes. A related issue has to do with (inherited) ethnic differences within the same community. A clear example is the United Kingdom, in which we can find a great deal of variation

 http://dx.doi.org/10.1016/B978-0-08-097086-8.54004-5

between standard and nonstandard forms of the English language, several indigenous languages (Welsh, Scots, Gaelic), and non-English languages brought to Britain by immigrants mainly from countries in the Commonwealth. In all cases, language is raised to a basic source of personal specificity against 'default' speaking correctness.

'Optional' Sources of Identity

Next in the inverted triangle of identity sources, a middle section of optional sources may be isolated. As human beings grow up, they tend to get together in medium-sized social groups providing an essential sense of belonging and often involving particular discursive features which work as inherent sources of intragroup identity and also as intergroup differentiation (the so-called jargons). A typical example is scientific discourse. Adolescents also display explicitly narrow codes of vocabulary choices and nonstandard pronunciations only available to those 'in the gang' or the group of peers. Furthermore, laughing is considered to be an important source of identity display in this age group through reducing the 'others' to some laughable characterization that makes them different to adults (Boxer and Cortés-Conde, 1997, p. 283); and insulting one another is also typical (Mateo and Yus, 2013), both strategies intended to enhance a deeper bonding between group members.

An important term in this medium-sized area of optional group membership is social network (Milroy, 1978), a way of representing people's social transactions within a speech community. This term is related to the importance of everyday interactions (especially with peers) for identity shaping. Bucholtz and Hall (2005) stress this with their *relationality principle*, i.e., identities as "produced through contextually situated and ideologically informed configurations of self and other" (p. 605). Kiesling (2006) stresses that a person has no single fixed identity because identities are relational, they are constructed, and contextualized in interaction. Also from constructivist approaches, identity has been regarded as a nonstable but inherently interactive phenomenon, since it takes place in specific interactional occasions, yields an array of identities instead of unitary selves, and mainly results from processes of negotiation that are eminently social (De Fina et al., 2006, p. 2).

Closely related to this issue are Le Page's (1986) *acts of identity*, a term which stresses the individual's tendency to try and resemble the linguistic attributes of those groups of people which he or she aims to identify with: "when we talk we project the universe as we see it on to others as on to a cinema screen in our own images, expressed in the language we consider appropriate at that moment, and we invite others by these acts to share our universe" (p. 23).

Discourse, Identity, and the Self

The speaker's interactional self would be placed at the bottom vertex of the inverted triangle. In this case, as suggested above, self-identity is shaped and modified by daily and ordinary conversational interactions. Interlocutors continuously negotiate a *relational identity* with and through others. Consequently, one's current (and past) conversational exchanges will shape or affect the relationship between participants and speakers' relational self-identity. Far from being a stable, unitary identity, one's identities change according to conversational roles and situations. This is why De Fina et al. (2006, p. 14) distinguish *discourse identities* (mainly the individual's roles during an interaction) from *situated identities*, which are instantiated in particular types of situations. But individuals also acquire a personal discourse-related identity in the shape of personal idiolect, defined as a "particular combination of accent and dialect, that particular assemblage of formal and informal registers, that particular pattern of stress and intonation which, if we were to look closely and cleverly enough, we would find unique to the individual" (Edwards, 2009, p. 21).

Analysis of the self as developed and affirmed through daily interactions and situations goes back as far as the 1950s, with *interactional sociolinguists* (Schiffrin, 1994), with Goffman (1959) as one of the main contributors to this trend of research. Goffman argues that the self is a social construction (specifically, an *interactive construction*). This is clearly exemplified by the identity-related notion of *face*, defined as the social value that speakers effectively claim for themselves in the course of a conversational interaction. What Goffman focuses on is the social value of conversational involvement, the way different social and conversational settings involve specific expectations and display of this involvement, which normally entails the use of certain ritualized forms of address. Schiffrin (1994) also includes Gumperz in the label of interactional sociolinguistics because of his view of language as a culturally constructed system and which can be used either in order to reflect macrolevel social meanings or to create microsocial meanings at the level of ordinary conversational exchanges.

Another trend of research which focuses on the social implications of daily conversational interactions is *ethnomethodology*, with Garfinkel as one of its main representatives. This trend focuses on the cognitive rules by which members of a society assess the significance of actions in everyday life. People's previous experience and their knowledge of the institutions and practices of the world around them act to constrain their interpretations of what they see and hear. Under ethnomethodology, conversational scenes acquire an essential importance in the display and shaping of self-identities, which are only knowable through the understandings displayed by the interlocutors themselves: "membership of a category is ascribed (and rejected), avowed (and disavowed), displayed (and ignored) in local places and at certain times, and it does these things as part of the interactional work that constitutes people's lives" (Antaki and Widdicombe, 1998, p. 1).

The main conclusion of this research is that people's self-identity is not a fixed feature of their lives, but a dynamic attribute continuously under negotiation, reshaping, transformation, as people engage in daily ordinary communication with others. When some social or cultural aspects are continuously brought into conversations, they tend to become attached to the identity of interlocutors as part of their background of group membership. For example, Georgakopolou (1999) focuses on identities of the young and how *peer networks* are created in the conversational repetition of specific elements in the discursive (sub)culture of the young. For them, symbolic cultural associations such as dress styles and others such as

music preferences, activity patterns, etc. are firmly located in their conversational interactions, especially in the unfolding of conversational narratives.

On the other hand, self-identity is also achieved in the feeling of personal specificity when contrasted with others in the course of a conversation. In this case, Davies and Harre's (1990) term *positioning* as 'discursive production of selves' is very interesting. They agree that self-identity is not fixed but constituted and reconstituted through the various discursive practices in which people participate. Positioning would be the discursive process through or within which people's selves are foregrounded in conversations. There can be *interactive positioning* in the sense that what one person says positions another, and *reflexive positioning*, when one simply positions oneself.

Markus and Nurius' (1986) theory of *possible selves* also deals with the way people acquire a sense of self-identity through the conversational interactions in which they participate. These possible selves represent the picture that all interactants have about what they are and what they would like to become. In this sense, possible selves influence people's future behavior and are a constant evaluation of people's current state of their self-identity. People's social and cultural contexts play an important role in this shaping, since the range of possible selves derives not only from people's personal experiences (e.g., prior conversational interactions), but also from categories which acquire prominence in a specific sociocultural and historic context, together with images and symbols provided by (highly influential) media discourses constraining the personal choices of self-identity.

Inverting the Inverted: Discourse and Identity on the Internet

In Yus (2001), it was argued that the inverted triangle of broad top (macrosocial issues), middle section (optional linguistic groups), and the vertex at the bottom of the triangle (personal self) was affected by the *global village*. In this environment, identity is viewed as "the process of construction of meaning on the basis of cultural attribute, or related set of cultural attributes, that is are given priority over other sources of meaning" (Castells, 1997, p. 6). The important conclusion is that people tend to react by reaffirming their historical, cultural, ethnic, and religious roots as a reaction against networked globalization.

The most paradigmatic example of a global communicative network is the Internet, which is so pervasive nowadays that it actually *inverts the inverted triangle*. First, the formerly broad section of inherited attributes at the top of the triangle is narrowed as a consequence of increasing transnational communication and depersonalization of networked transactions. Hence, national attributes may become blurred and their identity-shaping effect be weakened or invalidated; and other inherited features such as race and sex are suppressed in text-based interactions.

Second, the middle section of optional sources of identity, normally through self-socialization through interactions within groups shaped by specific linguistic patterns, remains more or less in the same medium-sized section of the triangle. On the Internet, these specific discourse groups with their limited-access jargons are reproduced in parallel forms of organization: the so-called *discussion forums* and (now almost extinct) *distribution lists* via e-mail, which also exploit the same sense of group-membership language specificity that we can find in offline social instances.

Third, the former narrow vertex of personal self in the inverted triangle has now become very broad due to the multiplicity of selves (often anonymous) that may be used in conversational exchanges through various forms of Internet communication such as *chats* or avatars in 3D virtual worlds. In the physical world, the body provides explicit (and stable) clues of inherited and personal qualities shaping the person's identity. On the Internet, however, these attributes are not explicitly conveyed, and one can have as many electronic identities and selves as one is willing and or able to create, all of which are presented with no corporeality. As Mitchell (1995) correctly states, the process of mutual construction of identities on the Internet usually gives very little away. Because communication often takes place without bodily presence or the sound of users' voices, others who 'know' a user quite well may not realize how he or she looks, and thus may be unable to make the usual inferences from that. On the Internet people can very easily conceal, leave carefully ambiguous, or falsely signal gender, race, age, body shape, and economic status.

A good example of these three layers in the 're-inverted' triangle is social networking profiles (e.g., in *Facebook*). The visual list of contacts exhibits broad community membership. The comments and posts area is where users put their relational identity into practice, often with peers (sometimes also in specific professional profiles). Finally, the personal photo and information is the locus of self-identity, the user as a unique person in the network of friends.

More recent research (Yus, 2007, 2010, 2011) acknowledges the fact that this picture of discursive sources of identity as triangles (inverted for physical identity; re-inverted for virtual identity) clashes with today's tendency to hybridization of personal networks in physical and virtual settings and with the users as nodes in intersecting networks. Therefore, it would not be a picture of 'either' physical 'or' virtual sources of identity, as can be deduced from two triangles that do not touch, but a picture of several sources of identity that mix and imbricate in a time when the dividing line between physical and virtual realms is increasingly blurred.

Indeed, today's Internet users have developed an ability to switch from offline to online networks of friends with different degrees of commitment and intensity depending on what portion of their identities is shaped discursively on the Net, ranging from those who rarely log on, to those who reject their physical identities entirely and can only 'be themselves' on the Net. And environments such as social networking sites and, more recently, 3D virtual worlds are suitable environments for discursively shaped identities. Specifically, social networking sites are typically used by people who already know one another offline, e.g., students or relatives (Mallan and Giardina, 2009; Wang et al., 2010, p. 227). In general, then, people do not turn into different people in either of the environments (offline/online), but provide a different image, divide their identities into physical and virtual sides of the self. The virtual self may exhibit attributes that the user does not want to show in physical settings, without losing the core

identity. As Zhao et al. (2008, pp.1819–1820) correctly state, "users regard their online presentations as an integral part of their overall identity production and seek to coordinate their online identity claims with their offline self-performance."

In any case, in my opinion it is interesting to preserve a threefold division of identity and analyze the extent to which discourse (in its broad sense of textual, visual, and multimodal quality) plays a part in virtual identity shaping. Needless to say, there is some degree of overlapping among the three. For example, in virtual worlds the users shape their identities by devising an avatar, but the choice of body and clothing is often biased by cultural (i.e., collective) information about sex roles, masculinity, femininity, and beauty.

First, the collective identity is shaped by discursive markers that indicate membership to broad (online/offline) collectivities and communities. "It is through our membership into various social groups that we discover and experiment with social identities in the hope of creating an image of ourselves that is acceptable to the social realities we are invested in" (Crabill, 2010, p. 316). As stated in Yus (2011), people store a number of commonsense assumptions that emanate from the human environment and our trust in these assumptions is not easily altered by other in-coming stimuli. The fact that we belong to a specific speech community entails the creation and storage of certain archetypical assumptions that we accept as *normal* or *default* in the ordinary life of the community (Yus, 2007; Parks, 2011, pp. 106–111). And conversations are a good means to determine this area of mutuality. Besides, the reiterative assessment of this area generates community stereotypes, made up of highly accessible stereotypical schemas.

Second, the group identity is shaped through interactions with other users and by choosing to belong to certain groups and collectivities that exhibit certain patters and jargons that enhance discursive specificity. By receiving comments and engaging in interactions, that is, by being present in the network and being commented upon by others, users mold their position and prestige within the group.

Finally, self-identity reflects the fact that the user is a unique person discursively shaped on the Net according to specific parameters. It is related to the *self-concept*, but also shaped in a public process that involves both the *identity announcement* made by the individual claiming an identity and the *identity placement* made by others who endorse the claimed identity (Zhao et al., 2008, p. 1817). The user's body is essential for the foundation of this self-identity, even if only part (or none) of it is actually exhibited on the Net. Of course, one can also avoid the body completely and play with other selves and corporeal fabrications (as happens with 3D avatars) that might also play a part in the overall self-identity shaping. But other users will probably try to make connections between the persona exhibited online and the physical self typing on a keyboard (Walther et al., 2009, p. 232).

In some specific situations, though, real-life and virtual-life selves may overlap, creating, in extreme cases, problems of self-identity when one is unable to dissociate the physical and the virtual. In normal circumstances, though, our online selves become just one more series of selves in our everyday lives that we create in order to deal with a variety of situations.

Specifically on the relationship between discourse and identity, identity construction on the Internet is still text-based on many occasions, normally through a hybrid between the permanence and fixed quality of written texts, and the spontaneity and ephemeral status of oral utterances (Baron, 2000; Tella, 1992). Beyond the evident problems that text-based interlocutors face in the course of a conversation due to the lack of contextual support, the increasing appeal that *chats* and other interactive online phenomena have nowadays should make us think twice before claiming that the oral medium is undoubtedly superior to the written medium. The profusion of written messages that people exchange through mobile phones nowadays, for instance, is a clue suggesting that, perhaps, people are still willing to construct and communicate identities through language, but perhaps not so much through face-to-face encounters, even though today there are more and more options for synchronous face-to-face interactions involving visual and vocal channels.

Abstract

Although the concept of discourse has played a significant role in anthropological research since the 1980s, competing framings as an analytic concept or object of research have sometimes given rise to nonoverlapping, or even acrimonious conversations. Beginning in the 1990s, interest in ideologies of language, practice theory, and issues of scale prompted increasingly productive exchanges across subdisciplines and perspectives. Recent respositionings of discourse both as analytical concept and a focus of research on shifts of capital, culture, and language in contemporary landscapes sparked a proliferation of research on discourse and its frequent assimilation as a mundane component of research frameworks.

Introduction

Anthropology, particularly in France and the United States, has been shaped at various points by what has often been referred to as a 'linguistic turn,' reliance on models of language for theories of culture and society. Franz Boas, for example, used phonetic variation in explaining cultural variation; he suggested that just as each language selected a small range of sounds from a practically unlimited array and arranged them in unique ways, so culture mapped the infinitely varied range of personal experience onto a limited range of categories. This line of reasoning was extended by Edward Sapir and Benjamin Lee Whorf. In the 1960s and 1970s, Claude Lévi-Strauss drew on Roman Jakobson's and Morris Halle's distinctive feature model of phonology in creating varieties of structuralism that revolutionized anthropology, literary criticism, and other fields. During the last several decades of the twentieth century and in the twenty-first, the concept of discourse gained force in organizing research in the discipline. This article traces both the shifting ways that anthropologists have used the term and its sometimes powerful and precarious ability to organize points of scholarly convergence and divergence.

At first glance, the centrality of the concept of 'discourse' in the work of many anthropologists and other scholars in the 1980s and 1990s might seem to have represented another linguistic turn, a new convergence of linguistic and social/cultural perspectives. Nevertheless, the effect was often the opposite. Practitioners influenced by poststructuralist and postmodern theories often followed Michel Foucault in "treating discourse [not] as groups of signs…but as practices that systematically form the objects of which they speak" (1972: 49). Many linguistic anthropologists, on the other hand, challenged structuralism by emphasizing context, variation, and discursive practices; the concept of discourse was appealing as a rallying cry for going beyond decontextualized analysis of isolated signs to the analysis of communicative acts as they are embodied in specific situations. Although the latter practitioners defined discourse – generally implicitly – in a variety of ways, most associated the term with bounded texts, conversations, and electronically mediated messages, and analyses generally focused on details of form, content, and context. The result was the creation of divergent bodies of literature that carried the banner of discourse but that often had relatively little to say to one another.

With the turn of the new millennium, this polarity seemed to give way to a variety of modes in which 'discourse' became assimilated to diverse perspectives. In some cases, such as critical discourse analysis (CDA), 'discourse' provides a central analytical term. In many other instances, discourse seems to have become a relatively mundane element of a lexical stock in trade. Recent research has also explored how neoliberal transformations have focused on discursive practices as forms of labor and modes of producing value.

Discourse after Structuralism

A number of writers turned scholarship on its head in the 1960s and 1970s. Previously, academics had often claimed an epistemologically superordinate position, framing their analytic concepts and methods as privileged devices that seemed to stand above or beyond the constraints of the social actors or texts they studied. Poststructuralism challenged such claims, placing scholarship squarely into the middle of the politics of social life. Playing a key role in continually producing what were characterized as modern subjects, philosophical, and academic texts became a central object of analysis itself. Jacques Derrida suggested that concepts of language, culture, aesthetics, and so forth were in need of 'deconstruction,' of playful and irreverent analyses that unraveled the powerful illusions that imbue dominant frameworks with authority. While Lévi-Strauss characterized culture as based on unconscious oppositions, Derrida revealed the magical acts that he and other scholars used in creating these sorts of dichotomies and making them seem real.

The influential writings of Michel Foucault (1972) brought the term 'discourse' and an orientation toward 'the archaeology of knowledge' to the fore in a wide range of disciplines. He suggested that we must examine how "effects of power circulate among scientific statements, what constitutes, as it were, their internal régime of power" (1980: 112). Foucault did not identify discourse with particular utterances or texts, and he argued that it is not possible to grasp the power of discourse when it is seen as rooted in a particular context, viewed as an isolated and self-sufficient totality. He rather suggested that "a statement always belongs to a series or a whole, always plays a role among other statements, deriving support from them

and distinguishing itself from them" (1972: 99). One of his major contributions was demonstrating that institutions form key loci for the production and legitimization of discourses, and he identified how they are embodied in 'political technologies' that create schemes of surveillance and regulation in such settings as prisons, clinics, and asylums.

Foucault's work has been criticized for focusing on dominant texts, thereby reproducing the marginalization of contributions by women, racialized populations, and people outside of Europe. Particularly in his early work, Foucault seems to go against his disavowal of structuralism and his call to look beyond the dispersion and mutability of elements of discourse in favor of finding of "a unity …[that] resides, well anterior to their formation, in the system that makes possible and governs that formation" (1972: 72).

A complementary point of departure was provided by attempts to reverse the long history of attempts to reduce rhetoric to forms of ornamentation and techniques of persuasion, a central bête noire during the time of the emergence of modern science in the seventeenth century (Bauman and Briggs, 2003). Hayden White analyzed historical texts as narratives, suggesting that how historians construct the past involves two steps – an act of imagination that creates a vision of the past and a subsequent act of rhetorical magic that renders the imaginary real, convincing audiences that that is just the way it happened. Attending to issues of both rhetoric and power, practitioners have critically examined how anthropology similarly contributed to continual reproduction of categories of racialized Others. James Clifford and George Marcus (1986) and other writers dissected 'the poetics and politics' of anthropological texts, particular rhetorical strategies that ethnographers used in imagining 'the field' and imbuing their constructions with authority and authenticity. When viewed critically as power-laden discourse, ethnography became suspect, particularly in the eyes of scholars in cultural and ethnic studies. Unfortunately, classic deconstructions by such scholars as Américo Paredes (1993[1977]) of ethnographic rhetorics that stereotyped racialized minorities were seldom cited as precedents.

Anthropologists have also detailed how complex, multifaceted, and contested relations are discursively transformed into seemingly simple dichotomies, such as savage *vs* civilized and traditional *vs* modern, through colonial discourses. By revealing the complicity of ethnography in colonial regimes and the colonial underpinnings of contemporary anthropology, scholars deepened the critique of fundamental anthropological concepts and practices. Michael Taussig (1987) drew on the work of the Frankfurt School in revealing the way that the production of racialized images went hand in hand with the violent oppression of indigenous Latin Americans. Students of colonialism and others have turned to theorists who come from outside the Euro-American orbit, including the Subaltern Studies group in India and such Latin American theorists, as Néstor García Canclini (1995[1989]), for points of departure.

Finally, a number of scholars responded to analyses of the 'free floating' character of postmodern discourse by experimenting with techniques of ethnographic analysis and writing. Anthropologists sought to disrupt dominant rhetorical strategies and political positions by creating ethnographic and other texts that drew on surreal, fictional, and other techniques. The idea that both culture and ethnography are dialogic, tied to M.M. Bakhtin's conception of discourse, has influenced many of these innovations. Concern with cultural discourses were thus translated into attempts to a range of strategies for transforming anthropological discourses of culture.

Linguistics Approaches to Discourse

Other scholars used the concept of discourse to grapple with limitations in existing approaches to language. Structural linguists largely followed Ferdinand de Saussure in constructing languages as quintessentially embodied in closed systems of context-independent signs that stand apart from politics, history, and social differences between speakers. Noam Chomsky pushed many linguists toward even more formal, abstract approaches and further marginalized the study of linguistic heterogeneity by positing an ideal speaker–listener as the model of the subject of language. An orientation toward discourse promised to free practitioners from focusing exclusively on referential relations as encoded in small, decontextualized units in favor of studying the way that texts, conversations, and entire genres were embedded in social life. In opposition to poststructuralist and postmodern rejections of 'positivistic' definitions, many linguistic anthropologists envisioned discourse as a means of achieving greater empirical scope and depth.

Beginning early in the twentieth century, 'Russian Formalists' focused on such discursive units as stories or poems, detailing how writers played with linguistic forms apart from or in playful relationship to their semantic content. The Prague School developed a dynamic approach that emphasized expressive, appellative, and aesthetic functions in addition to the referential function and examined how they intersected in different each genres. Roman Jakobson figured prominently in the development of both of these approaches. He drew on an account of semiotics devised by philosopher Charles S. Peirce, one that emphasized types of signs that revolved around existential relationships to particular contexts and nonarbitrary resemblances between sign vehicles and their objects as well as context-free symbols.

Russian V.N. Vološinov (1973[1930]) took on Saussure directly, drawing attention to the capacity of signs to link multiple contexts, voices, and texts and detailing the special role of reporting the words of others in creating this multiplicity. While Saussure viewed discourse in its particularity as only a point of departure for abstracting underlying systems of signs, Vološinov centered analysis on the utterance. M.M. Bakhtin (1981) characterized discourse as heteroglossic, suggesting that languages are not closed, stable systems but points of intersection between competing structures, styles, genres, voices, and perspectives. Rather than the sources of social consensus – and national unity – that Saussure had envisioned, languages became sites of struggle. British philosopher J.L. Austin (1962) transformed received understandings of the relationship between word and world by arguing that utterances are performative – that they do not simply refer to real world events but create them; saying, in short, is a form of doing. Linguists have mapped the grammatical and 'discourse level' features of texts and genres and tied them to communicative functions, as in Michael Halliday's systemic-functional approach.

In the 1960s and 1970s, American scholars drew on these insights in challenging dominant structuralist and transformational (Chomskyian) approaches. Dell Hymes (1974) called for an 'ethnography of speaking' that documented the social and cultural patterning of language in its social context. While Saussure and Chomsky banished linguistic variation, the way that forms and meanings vary between speakers and contexts, from serious linguistic study, Hymes and other scholars placed it at the center of an emerging sociolinguistics. A generation of practitioners who obtained their PhD's in the late 1960s and early 1970s conducted ethnographies of speaking that focused on such issues as gender, political and religious ritual, rank and status, and expressive genres. Richard Bauman and other writers illustrated how this approach can be used as a tool for historical analysis. In the mid-1970s, Bauman (1977) and Dell Hymes (1981) complemented the emphasis on poetics generated by Roman Jakobson and other scholars by focusing on performance. William Labov developed a varationist sociolinguistics that mapped the social distribution of language varieties and the expressive functions of these differences. John Gumperz (1982) crafted an approach to interactional sociolinguistics that looked closely at conversational inferences made by persons engaged in face-to-face interaction and contextualization cues, dimensions of discourse that speakers use in shaping and interpreting contexts. Aaron Cicourel (1974) analyzed sociological research as discourse, conducting ethnographic research on surveys and other techniques in ways that revealed how claims to validity and reliability are based on complex interactional work that is generally rendered invisible as the analysis proceeds. Michael Silverstein (1976) drew on the work of Charles Peirce and Roman Jakobson in developing a 'metapragmatic' approach that complements the study of semantics with rigorous attention to the centrality of indexes that position discourse in relation to existing social contexts – and create new contextual parameters. The frameworks these scholars developed helped to focus attention on linguistic diversity and language policies in contemporary nation-states, presaging later interest in discursive dimensions of nationalism, power, conflict, and social inequality. They placed questions of communicative functions – the multiple roles of language in shaping social life – alongside those of structure at the center of inquiry.

Other scholars working in the United States sought to draw the study of discourse away from the study of types, rules, norms, and functions; they defined discourse as – and limited objects of analysis – to particular stretches of talk. Sociologists Harold Garfinkel and Erving Goffman argued that discourse should be studied not as an end in itself but as a window on social interaction. Garfinkel's concern with everyday, mundane encounters was placed at the center of the field of conversation analysis, which proclaimed "an insistence on the use of materials collected from *naturally occurring* occasions of everyday interaction by means of audio- and video-recording equipment or film" (Heritage and Atkinson, 1984: 2; emphasis in original). Emanuel Schegloff (2006) rejected analytic recourse to contextual information that did not appear in the audio or video recording itself; conversation analysts scrutinized transcripts for regularities in the sequencing of conversational features. Many practitioners focused on institutional contexts, detailing the role of interaction in shaping what takes place in courtrooms, schools, clinics, and other settings. Joel Sherzer proposed a 'discourse-centered' framework that similarly privileged 'naturally occurring and recorded speech' (1983: 10) at the same time that he called for systematic attention to broader social and cultural contexts. Such approaches represent an opposite pole from poststructuralist frameworks in that they view discourse in maximally empirical terms and focus on minute analysis of recorded talk.

Intersections: The Politics of Discourse

In short, the life history of 'discourse' in anthropological writing during the 1980s seems to follow a number of distinct, semi-autonomous trajectories. When paths intersected, they often generated examples of boundary-work, efforts to heighten differences between approaches and defend academic turf; debates sometimes developed acrimonious overtones. Although it would not be difficult to locate instances of this trend up to the present, the 1990s seemed to give way to interest on the part of many anthropologists and other scholars on the role of discourse in shaping power and the politics of difference, resulting in a number of important intersections between practitioners who formerly held opposing views of discourse.

Pierre Bourdieu (1991) placed sociolinguistic scholarship into a framework that defined types of linguistic competence as 'symbolic capital' in seeking to reveal the role of discourse in processes of 'symbolic domination.' He redefined the concept of communicative competence in such a way as to draw attention to the barriers of class and race that limit access to sites in which such competence can be acquired. Aaron Cicourel, Charles Briggs, Elliot Mishler, and others have focused on interviews as social as well as communicative events, detailing how formal and contextual features shape and are shaped by power asymmetries, thereby creating discourses that scholars use in imagining social life and imbuing their texts with authority and authenticity.

Bakhtin (1981) emphasized the heterogeneity of discourse and how it is constantly in movement, even within what seems to be a bounded, fixed text. John Gumperz (1982) urged concern with how contextual parameters are continually made, differentially interpreted, and sometimes contested in social interactions, particularly as they cross perceived boundaries of race and class. In the 1990s, linguistic anthropologists attempted to account for the complexity and instability of relations between texts, contexts, voices, and subjects. Richard Bauman and Charles Briggs (1990) proposed a framework for analyzing how entextualization uses formal and referential dimensions in such a way as to project a process of decontextualization from antecedent texts, contexts, genres, and persons, simultaneously projecting discourse forward in terms of how it may or must be recontextualized. Michael Silverstein and Greg Urban (1996) focused on entextualization as a dynamic process in which discourse gets reified as texts, thereby taking on social lives that shape and are shaped by the sites, voices, social processes, and other dimensions of cultural worlds in which they come to be repositioned.

Building on Silverstein's foundational work, linguistic anthropologists have explored the role of language ideologies, socially situated conceptions of the nature and functions of language, speech, and communication, in shaping both

linguistic structure and social life (see Schieffelin et al., 1998). This work fostered conversations across subdisciplinary boundaries as linguistic anthropologists used the concept of language ideologies in exploring problems of central interest to sociocultural anthropologists and other scholars by demonstrating the central role of social constructions of language, text, and talk in shaping notions of gender, race, religion, space, the body, and democracy.

This work sometimes took a historical turn. Judith Irvine examined a language of linguistic kinship in tracing how 'language families' became a central framework for colonial projects in Africa. William Hanks (2010) argued that Mayan languages emerged in the context of colonialism rather than as pristine autochthonous voices; just as they structure modes of transforming indigenous societies, literacy practices provided Mayan elites with ways of appropriating forms of colonial authority. Bernard Cohn, Nicholas Dirks, Gloria Raheja, and others have explored how deeply, in Cohn's (1996) terms, 'the language of command and the command of language' were inscribed in British colonialism in South Asia. Bauman and Briggs (2003) examined the centrality of ideological constructions of language to shifting projects of modernity, arguing that John Locke's separation of language from natural and social worlds in the seventeenth century was as crucial for creating social categories, policing boundaries, and naturalizing forms of inequality as the nature *vs* culture, science *vs* politics 'Great Divide' that formed the focus of research by science–technology–society studies' scholars. Webb Keane (2007) suggested that what he referred to as 'semiotic ideologies' crucially informed Dutch Calvinist missionization in Indonesia, teaching colonial subjects the proper boundaries between subjects, texts, and objects.

The ideological construction of multilingualism similarly provided a fruitful arena of research. Kathryn Woolard (1989) pinpointed how the enactment of 'English only' laws and other legal mechanisms could rally conservatives and liberals, Latinos/as and non-Latinos around seeing Spanish in the United States as a threat to equality and democracy. In sensitive studies that located what seemed to be problems created by Spanish/English bilingualism in New York City, Bonnie Urciuoli (1996) and Ana Celia Zentella (1997) pointed to ways that dominant language ideologies and institutional practices naturalize structural inequities by constructing working-class Spanish–English bilinguals as lacking competence in either language, viewing their seeming linguistic incompetence as a cause of their racially subordinate position. Monica Heller (2006) charts the complex politics and economics of French–English bilingualism in Canada. Nicholas DeGenova (2005) and Hillary Dick (2011) analyze both discourses of (im)migration and how discursive ideologies and practices construct the categories of 'native,' 'immigrant,' and 'illegal alien.' Norma Mendoza-Denton (2008) uses both quantitative and qualitative variationist sociolinguistic studies and an ethnographic exploration of bodily constructions in interrogating a popular construct, 'Latina gang members.' Jane Hill (2008) analyzes faux bilingualism, the purportedly playful use of what seem to be Spanish expressions by monolingual English speakers. Hill analyzes the role of mock Spanish in reproducing whiteness and naturalizing neoracism ("I'm not racist, but…"). Leo Chávez (2001) and Otto Santa Ana (2002) look respectively at visual and textual representations of Latin American migrants to the United States as a flood of racialized, inferior, and alien bodies.

Anthropologists and other scholars responded to Jurgen Habermas's work on the construction of a modern 'public sphere' in which citizens debate discourses that shape social life and political institutions by detailing the way that dominant forms and arenas are contested by resistant voices and counterpublics. Such investigations have helped to illuminate the processes by which limits are imposed on what sorts of things can be said and who can legitimately say them. Linguistic anthropologists drew attention to ways that public constructions of languages and linguistic diversity crucially inform the processes of making publics (Gal and Woolard, 2001). Anthropologists have explored the powerful role of such communication technologies as newspapers, gramophones and phonographs, radios, and television in producing publics and types of political subjectivity, responding to Jesús Martín Barbero's call to attend to forms of mediatization that help produce constructions and experiences of the social rather than beginning with received notions of 'media' and 'society.'

CDA grew out of linguistics with a focus on issues of power and social/political domination. While some varieties, such as the work of Teun van Dijk, have focused primarily on features of media and other publicly circulating texts, Norman Fairclough incorporated social theory and emphasized the importance of studying 'discourse-as-discursive-practices' and 'discourse-as-social-practice' as well as 'discourse-as-text' (1992). One of the major foci has been discursive dimensions of racism; given the location of many CDA scholars, racism in Europe and the UK has been a major focus. For example, Jan Blommaert and Jef Verschueren (1998) examined the representation of immigrants in news accounts, and Ruth Wodak focused on the discourse of the far right in Europe (Forchtner et al., 2013).

One focus in linguistic anthropology in the opening decade of the twenty-first century was on linking language ideologies to interactional practices, detailing how representations of language varieties, speakers, speech acts, and ongoing speech interact closely with pragmatic details yet without ever determining or fully mapping them. Silverstein (2004) pointed to the need to grapple with issues of scale by linking the study of these relations in recordings of conversations and broad features of social life. Asif Agha (2007) explored how complex interrelations between language and social relations shape models of conduct, suggesting how shared interpersonal engagements realized through everyday language use shape the emergence of difference, contestation, and differential value. Ben Rampton's (1995) notion of crossing explores how people in multiracial settings use language varieties associated with populations to which they do not belong. Charles Briggs (2005) looks at the circulation of discourse both in terms of observed practices, circuits, and mediatized processes and what he refers to as communicability, the competing cultural models that project how discourse is produced, how it travels, and how it is received.

The Dispersion of 'Discourse' in the New Millennium

The last decade or so has witnessed the emergence of a host of conversations in which discourse both figures in the

articulation of analytic perspectives and becomes an object of analysis. J.L. Austin's attention to performativity was refocused through the work of Derrida (1977[1972]); work on gender and sexuality by Judith Butler (1993) placed the body centrally into discussions. Linguistic anthropologists have contributed in many ways to rethinking the place of language and discursive practices in the production, performance, and contestation of gendered and sexualized bodies, voices, and subjectivities. At the same time that William Leap (1996) called for documentation of the speaking practices of gay men, Mary Bucholtz (2003), Mary Bucholtz and Kira Hall (1995), Deborah Cameron and Don Kulick (2003), and Bonnie McElhinny (2007) have drawn on feminist and lesbian, gay, bisexual, transgender studies in pointing to more complex relationships between gender, sexuality, and language and challenging patriarchal and heteronormative assumptions about language, subjectivity, and social life. Work such as Norma Mendoza-Denton's (2008) study of Latina gangs examines how discourse, bodies, race, and sexuality intersect.

One of the most visible arenas of anthropological research in recent decades has involved a focus on science, medicine, and the body. This rapidly expanding field of research, which cannot be effectively summarized in a few lines, has explored how discourses of aging, HIV/AIDS, sexuality, epidemics, pharmaceuticals, genetics, reproduction, addiction, mental illness, and scientific evidence have circulated alongside technologies, practitioners, bodies, organs, drugs, disease, humanitarian organizations, and regimes of health, security, and preparedness. A shift from medicalization to biomedicalization links transformations of communicative, clinical, and public health infrastructures through posthumanist frameworks that create a multiplicity of nature/culture/technology amalgamations. Here, nonetheless, boundary-work seems to obstruct the development of more fruitful collaborations as work on these topics emerging within linguistic and medical anthropology tends to travel through parallel circuits separated by specialized vocabularies. Veena Das's (2006) work on narrative, violence, and bodies, which focused on the Partition of India and Pakistan and anti-Sikh riots, pointed to the rich potential of simultaneously attending to both *Life and Words*.

Much research has explored transformations of discourse associated with late modernity and neoliberalism. Critiques of previous anthropological work on globalization fostered a range of perspectives that queried how discourses, people, commodities, technologies, and epistemologies circulate as well as the metaphors and frameworks that scholars used to track them. Anna Tsing (2005) argued for a more nuanced metaphor of 'friction,' while Aihwa Ong (Ong and Collier, 2005) and Saskia Sassen (2006) suggested 'global assemblages.' Webb Keane (2007) argued that separating discourse from materiality is itself a reflection of semiotic ideologies of modernity. A number of anthropologists have recently explored the commodification of discourse and discourses of commodification through, for example, advertising (Dávila, 2001; Mazzarella, 2005) and ethnicity (Comaroff and Comaroff, 2009). Anthropologists and ethnomusicologists have traced the commodification and circulation of musical forms; Steven Feld's (2000) analysis of world musics and Samy Alim's (2006) research on hip hop draw attention to the diversity of analytics and assessments. Charles Hirschkind (2006) and other anthropologists have contributed centrally to shifting the locus of attention on performativity from an exclusive concern on speaking and writing to a focus on listening, which requires attention to bodies, technologies, and materialities.

The proliferation of sites, technologies, and practices associated with the digitalization of discourse have become the focus of much research. Countering initial formulations that often projected new communicative technologies as possessing the power to produce new ideologies, cultural configurations, social relations, and political economies, many authors have examined dimensions of remediation, seeing how perspectives and practices associated with prior technologies are repositioned alongside novel forms. Ilana Gershon (2010) traced the role of Facebook in how couples are formed and break up, examining the way that face-to-face interaction comes to be seen as just one more communicative possibility in an array of Internet- and social media-based modalities. Studying the world of on-line games ethnographically, Tom Boellstorff (2008) argued that such forms of virtual embodiment provide sites for rethinking dimensions of gender, sexuality, race, the material, and sociality itself. Dominic Boyer (2013) scrutinized the ongoing transformation of journalists from beat reporters on the street to office-based screen workers who focus less on the production of knowledge than on managing vast, multiple, and rapidly circulating bodies of discourse.

Finally, recent work on globalization and neoliberalism has challenged scholars to address issues of scale and complexity in both perspectives on discourse and how discursive sites and practices are documented and analyzed. Jan Blommaert (2010) pushed for new theoretical perspectives on mobility and modes of analysis that address both global connectedness and the emergence of new inequalities and forms of disconnectedness. A major focus of recent work in linguistic anthropology and sociolinguistics has been on language and/as labor, "where language is central not just as the process but as the product of work" (Duchêne and Heller, 2012: 13). Although call centers provide quintessential examples in which corporate strategies and digital networks script conversations enacted by workers living in areas where wages are lower, such 'language industries' include tourism, translation, surveillance, media, and language schools as sites where linguistic competence, discursive practices, and language ideologies are commodified (see Urciuoli and LaDousa, 2013).

Conclusion

It has been a daunting task to sort through the many ways that notions of discourse have been developed in anthropology. After gesturing at the vast discussions of concepts of language and culture and their interrelations that emerged in the first half of the twentieth century, I have traced a number of trajectories in which discourse figured as a key locus for articulating anthropological positions and defending their borders against competing perspectives as well as points at which the term helped shape convergence on issues that interest a diversity of scholars. This last article of the story prompts me to end on a rather paradoxical note. The beginning of the new millennium

has witnessed the emergence of work that productively exploits the tension between construing discourse as scholarly concept and as object of analysis. The very fruitfulness of this move and the range of dimensions of human life that practitioners have queried have led, ironically, to broad assimilation of 'discourse' as a relatively mundane part of analytic languages in a number of types of scholarly practice.

Abstract

In Discourse Studies, discourse is typically seen as a social practice of participants communicating through linguistic and other semiotic resources in certain contexts. Researchers in this field often insist on the constitutive character of discourse for social realities, structures and subjectivities. This article discusses both discourse theories (e.g., poststructuralist, deliberative, critical realist strands) as well as the more empirical approaches in discourse analysis (e.g., semantic and pragmatic, qualitative and quantitative strands). Special mention is made of developments in the West, notably in France and the UK, where Discourse Studies first started to emerge around 1970.

Introduction

In the last 50 years, 'discourse' has become a key notion in the interdisciplinary debate on the social sciences and humanities. Researchers who deal with discourse typically investigate the ways in which social realities are constructed through communicative practices. While many researchers who refer to discourse in their disciplines share an interest in language, communication, and meaning-making as central problems in contemporary society, 'discourse' is increasingly becoming the common denominator of a new, transdisciplinary field: Discourse Studies.

Discourse Studies has progressed as a reaction to developments both inside and outside the academic domain. Thus, developments of great topical relevance have accompanied the emergence of Discourse Studies: discrimination against social groups in the mass media, market-based modes of governing large populations, postnational regimes of exclusion in global postmodernity, the crisis of representation in culture and politics, and new technologies of surveillance and control.

If linguists with a social sciences background have, crucially, contributed to this field, many discourse researchers come from other fields in the social sciences and humanities (e.g., sociology, political science, history, philosophy, literary criticism, geography, education, economics, psychology, etc.). Established in France in the late 1960s and in the UK in the 1970s, Discourse Studies is today growing rapidly in many parts of the world, notably in Latin America and in China.

In Discourse Studies, researchers typically mobilize analytical and theoretical resources from the entire spectrums of the social sciences and humanities in order to account for the social production of meaning. Situated within the transdisciplinary space of language and society, Discourse Studies overlaps with a number of other fields such as pragmatics, sociolinguistics, semiotics, rhetoric, conversation analysis, linguistic anthropology, philosophy/sociology and so on of language. Among the characteristic features of discourse research, one can detect a focus on these questions:

- *Discourse as a sociohistorical meaning-making practice in context*. Meaning is not inherent in the signs, utterances or other semiotic resources that discourse participants use to communicate with each other. It is a product of linguistic and communicative practices whose meaning is inextricably tied to their contexts, material mediums, physical settings and participating bodies in and through which discursive practices occur.
- *The societal relevance of themes and topics*. While discourses can cover a wide range of domains, they often touch on questions and problems of special societal relevance, notably the existential moral and political questions of larger communities. Discourses tend to deal with knowledge circulating across many different contexts, mobilizing considerable resources and power and established through social institutions. Thus they often have an impact beyond the local and specific contexts in meaning-making activities that take place.
- *The discursive construction of subjectivity*. Even though discourse is considered to be a social practice, it does not presuppose that the discourse participants are always free to say and think what they want. On the contrary, their discursive practice is subject to rules and constraints which they do not always control. While discourse typically exceeds what they mean to say, think, or do, they become subjects only by entering discourse. Subjects, actors or agents are, themselves, a discursive effect of discourse, and not its origin.
- *Discourse as constitutive of the social*. From a discourse point of view, social structures are produced by meaning-making activities involving the use of language. At the same time, discursive practices are shaped by social structures. Discursive practices not only represent the social world but, in certain cases, they also constitute it – think of the act of ordering a beer in a pub, which creates rather than describes the relationship between customer and bar man, or the publication of statistics on smoking patterns, which can make a social problem real and objective for society.

While, in a most general sense, discourse deals with the social production of meaning, its meaning can vary: from discourse as text-based communication in large communities (especially among discourse researchers from Europe) to discourse as situated talk or turn-taking process in a setting (especially among discourse researchers from North America). The problems of discourse researchers can vary according to their disciplinary background: while linguistic discourse researchers usually want to go beyond the abstract – pure, internalist conceptions of language of classical structural or Chomskyan linguistics – sociologists and political scientists have turned to discourse in order to point out the symbolic construction of actors and 'reality.' Even though Discourse

Studies, just like sociolinguistics, has long been a subfield of linguistics, it is now becoming a transdisciplinary field at the crossroads of language and society, one which mobilizes theories and methods from all corners of the social sciences and humanities in order to study the ways in which linguistic, semiotic, and communicative resources and practices are mobilized in social communities to represent and constitute social phenomena (such as subjectivities and identities, relationships and structures, hegemonies and ideologies, knowledges and ideologies).

To account for the development of Discourse Studies in the last 50 years, this article will concentrate on (1) strands of (a) discourse theory and (b) discourse analysis and discuss (2) Discourse Studies as a global field.

Discourse Studies as Theory and Analysis

Discourse Studies is organized around characteristics split between two ideal-typical strands: one focussing on discourse as an intellectual and epistemological problem of social, political and cultural theory, the other on the analytical and methodological challenges of studying discourse as a material and empirical object (Angermuller et al., 2014b). Even though the term 'discourse analysis' is often claimed by both groups, one might suggest reserving 'discourse theory' for the former and 'discourse analysis' for the latter. If Discourse Studies has precisely emerged from the productive encounter of both theory and analysis, this distinction may help to explain some of the obstacles that have prevented the exchange between certain researchers claiming to deal with 'discourse.'

Discourse Theories

Within discourse theory, one can distinguish between at least three strands: post-structuralist, normative–deliberative and critical–realist discourse theories.

- Post-structuralist discourse theory usually insists on the constitutive role of language and communication for what counts as real in a given society. Thus, if the 'speaking subject' is seen as an effect of discursive practices, discourse not only describes but to a certain degree also constitutes the social. Rather than as a closed container, the social is perceived as an open, dynamic and heterogeneous terrain of relationships. Following Saussure's primacy of difference over identity or Wittgenstein's practical turn in social theory, post-structuralist discourse theory adopts a resolutely antiessentialist stance which emphasizes the contingent character of reality and nature constructed through practices involving both power and knowledge. While a first wave of post-structuralist discourse theory, among which Michel Foucault (1972) and Michel Pêcheux (1982), helped to constitute Discourse Studies in France, a second wave, also known as (*French*) *Theory*, resulted from the reception of 'Continental' thinkers (i.e., mainly from France such as Michel Foucault, Jacques Derrida, Jacques Lacan, Louis Althusser, Gilles Deleuze, Félix Guattari and to a lesser degree from Germany such as Friedrich Nietzsche, Walter Benjamin, Martin Heidegger, Theodor W. Adorno) in the Anglo-American world, where it has contributed to the formation of cultural studies (Hall, 2003), postcolonialism (Spivak, 1988; Said, 1978), the theory of hegemony (Laclau and Mouffe, 1985), queer studies (Butler, 1990), and psychoanalytical theory (Žižek, 1989).
- For normative–deliberative theories, discourse designates the negotiation of an agreement between participants who enter discourse in order to overcome a conflict while pursuing certain interests and objectives. Discourse in this sense usually involves free deliberation in the public sphere over what can be considered good and acceptable for all. According to this perception, the discourse participants need to come to terms with clashing norms in discourse. For the 'strong' program of normative–deliberative discourse theory, spelled out by third-generation critical theorists such as Jürgen Habermas (1985), certain communicative laws and normative standards are inherent in discourse which make certain claims more true, rational, and acceptable, whatever the social or political resources of those who make them. Weaker versions are typically critical of the universalism of the strong program and reject the idea of a normative point zero in discourse. They see hierarchies of values as discursive constructions of those who are concerned with social and political problems or as a contingent result of the communicative operations in an autopoietic system. Thus, Lyotard insists on certain unresolvable tensions and contradictions (*différend*) in discourse that can make rational agreement impossible (1983).
- While post-structuralist and normative–deliberative discourse theorists are firmly situated within the constructivist social sciences and humanities, some discourse theorists, who have defended a moderate realism, consider discourse to be a social practice embedded in given power structures. In this way, critical realist discourse theorists point to the objective social constraints in which discursive practices are embedded. Through discourse, unequal relationships are produced and reproduced between larger social groups, classes, or communities. Critical realist discourse theories usually have an affinity with macro-sociological theories of social and cultural inequality, ranging from the Marxist critique of ideology to Pierre Bourdieu's work on symbolic domination. In drawing from critical realist discourse theory, linguists have become interested in social problems in critical discourse analysis (CDA) (Fairclough, 1992), while Marxist sociologists (Sum and Jessop, 2013) have discovered discourse to be a constitutive dimension in the dynamics of social power.

While the common denominator of these ideal typical strands of discourse theory is the central role of language, communication, or meaning in social, political, and cultural theory, the line is not always easy to draw (Angermuller et al., 2014a). Thus, weaker versions of normative–deliberative discourse theories have often been associated with post-structuralism while Foucault's power/knowledge approach has been claimed by both post-structuralists and critical realists. The critical potential has been spelled out in all of these approaches, albeit in different ways: if the post-structuralist gesture is more epistemological, aiming at a subversive decentring of identities and 'naturalized' power, normative–deliberative discourse theories focus on the critical tensions between how discourses *should* operate and how they actually

do operate. Critical realism, finally, reveals the power structures hidden as it were beneath the representations produced in discourse.

In a word, discourse theories often articulate three problems: power, knowledge, and subjectivity, these are, visualized below in the discourse theory triangle. Accordingly, discourse is shaped by power structures but by representing power structures it can also contribute to objectifying and constituting them. As a socially-situated activity of producing meaning, discourse produces, establishes, and legitimizes knowledge in social groups and communities. And discourse is crucial for the construction of subjectivity as it defines, identities, and creates actorhood by attributing places and positions to those who enter discourse.

Discourse Analyses

While discourse *theorists* ask how linguistic models such as Saussure's differentialist theory of linguistic value or Wittgenstein's conception of 'language game' can inform social theory, discourse *analysts* deal with discourse as an empirical material object. If discourse theory has its base in social philosophy, macrosociology, or the constructivist political sciences, discourse analysis tends to have a background in linguistics or microsociological social research. To be a discourse researcher, one always needs to integrate both. However, some discourse researchers tend to be more at home on one side than the other.

From an ideal-typical perspective, analyzing a discourse usually means offering empirical insights into a socially and historically defined object (such as the 'War on Terror' discourse or 'classroom discourse in French *lycées*') on the basis of selected material (such as all the New York Times articles from 2000 to 2010 or the observation of classroom interactions). In discourse analysis, methodological tools are applied to selected material in order to generate empirically grounded hypotheses about the discourse to hand.

Discourse analyses do not have to follow classic research designs privileging 'hard' statistical methods, and they almost never believe in causalist epistemologies ("what are your dependent and independent variables?"). Discourse analysts are acutely aware of the fact that discourse is not a given object but rather partially constructed in the research process by methods and procedures which seek to account for the object. Discourse analysis in this sense mobilizes a broad range of methods, tools, and techniques which account for the uses of oral or written texts in specific contexts. Discourse analysis, therefore, does not designate a method but a cross-disciplinary field of methods and methodologies which investigate meaning making as a socially framed and situated practice.

Discourse analysis can work with quantitative or qualitative approaches, or both. Quantitative approaches usually rely on corpus analytical ('lexicometric' in France) methods, i.e., they deal with systematically selected and annotated textual material which is processed with the help of computer software. As a rule, quantitative tools are used for exploratory purposes to generate hypotheses about the macro-organization of a discourse which are then examined in more detail in qualitative microanalyses. If quantitative approaches usually deal with larger selections of written texts, qualitative approaches deal with smaller selections of material, written or oral, which can be handled 'manually' by the researcher.

Given that discourse analysis sees meaning as resulting from the interplay of texts and contexts, it must be strictly distinguished from content analysis, which views meaning as inherent in 'texts.' Discourse analysis, especially in its French and interactional varieties, must also be distinguished from hermeneutics in a narrow sense, understood as a subjective art of 'understanding.' While it places much emphasis on rationally describing the social production of meaning, discourse analysis shares the hermeneutic idea that in a wider sense, social phenomena are always meaningful. Thus, discourse analysis has a large number of tools, techniques, and procedures at its disposal which reveal the underlying rules and mechanisms of the discursive practices, resources and forms which are mobilized to realize a discourse.

A key problem of the modern social sciences and humanities discourse has been the object of many specialized approaches in the disciplines. Thus, linguists have catalogued the semiotic resources involved in discursive practices, sociologists have investigated the practical logics in discourse, anthropologists have paid special attention to settings, and so on. What makes discourse such a methodological challenge is that it is not a pure object. Discourse cannot be equated with texts, nor can it be reduced to a given context. Rather, the question is how to account for the (practical) uses that are made of language by certain people, at a given time, in a particular place. Therefore, the heterogeneous constitution of a discourse needs to be emphasized, which consists of different but interwoven 'components': 'language,' 'practice,' and 'context.' 'Language' comprises any repertoire of semiotic resources that can be mobilized in a discursive practice, that is, linguistic forms and expressions, words, utterances and texts, but also nonverbal signs and gestures, as well as visual, auditory, and olfactory signs; 'practice' denotes the practices people engage in to define their place vis-à-vis others and to coordinate their behavior. These practices can testify to their practical know-how and mobilize their resources (time, money, power, etc.); 'context' covers the socially defined situation or material setting in which discursive practice takes place. It can refer to the knowledge about who participates in discourse, when and where with what purpose and so on.

While these components always work together in discourse, discourse analysts sometimes prefer to take their point of departure from one angle rather than another. In this sense, 'language-oriented' discourse analysts, who are often but not always linguists, register linguistic or nonlinguistic material (for instance when it is shown in linguistic pragmatics how deictic expressions refer to their contexts) in order to account for how it is used in a given context. 'Practice-oriented' (or praxeological) discourse analysts prefer to observe what happens between actors in situations (for instance turn-taking processes in institutional talk). 'Context-oriented' discourse analysts focus on how material contexts (for example in an ethnographic study of intercultural communication in a setting) or on the question of how their contextual knowledge is constructed and established in discourse (for instance in a corpus analysis of the semantics of French nationhood). If each orientation starts from one angle which it takes as an empirically observable entry into discourse, discourse researchers always need to account for the other two components at least theoretically,

Figure 1 Discourse Studies as discourse analysis and discourse theory.

which is why they cannot always be easily distinguished. Without recognition of the articulation of all three strands, a language-oriented approach could become semiotic, a practice-oriented approach would be nothing more than conversation analysis, and a context-oriented approach might result in a mere interpretive coding of the themes and topics of a discourse. Therefore, unlike classical linguists who deal with language as an object per se, discourse researchers account for the practices employed by/in language in certain contexts. And unlike pure sociologists, they explain which practices are enacted and which knowledges are mobilized by linguistic forms. Just as discourse entails the interplay of language, practice, and context, discourse analysis involves a true cross-disciplinary perspective on the object, which is illustrated in **Figure 1**.

By articulating discourse theory and discourse analysis, Discourse Studies has crucially contributed to research on the social production of meaning in the social sciences. Yet it has not developed in the same linear way in all parts of the world. The currents and approaches which have received most international attention are situated for the most part in the Anglo-American world, France and Germany. According to a 'Continental' understanding, discourse designates written texts circulating in large communities whereas discourse as symbolic interaction taking place face-to-face is often considered to be more typical of the Anglo-American world. Linguists have played a leading role everywhere, especially in the more technical versions of discourse analysis; while discourse theorists in Europe are more likely to come from sociology, the political sciences, and philosophy, in the US they are mostly based in the cultural and literary field.

Discourse Studies as a Global Field

While Discourse Studies has recently seen dynamic growth outside the Western sphere, as a field, Discourse Studies was first established in Europe, especially in France and the UK, more so than in the US where 'discourse' remains a term used in a variety of specialized debates without designating a field with a common theoretical problem. Discourse Studies is probably most established in France, where it is, by and large, a subfield of linguistics, as well as in the UK and the former Commonwealth, where a number of high-profile schools are based (such as the Essex School of Hegemony and discourse analysis or the social semiotics inspired by Halliday, as well as many representatives of CDA). A large variety of journals as well as the regular recruitment of discourse researchers testify to the increasing institutional recognition that Discourse Studies enjoys in both countries.

From the beginning, Discourse Studies emerged in various countries and disciplines as the result of encounters between different traditions and schools. Today, there are no 'national' schools any more. Rather, in all countries there are discourse researchers who can be said to carry certain 'national' labels such as 'French' post-structuralism, 'American' interactionism, 'British' pragmatics, or 'German' hermeneutics. The following will give a brief overview of the major tendencies in the respective spheres.

Discourse Studies first started to develop in France, where it is known as *analyse du discours*, a name which goes back to an article by Zellig Harris (1952). As a field, it received seminal impulses from two theorists who started out as philosophers at the end of the 1960s, when the structuralist conjuncture in the French social sciences and humanities was drawing to a close: Michel Foucault (1972) and Michel Pêcheux (1982), the latter becoming the head of what is sometimes called the 'French School of Discourse Analysis' in the 1970s. In what followed, the field developed from the conjunction of the intellectual and political essence of discourse theory with two highly technical strands in discourse analysis, namely lexicometrics, which began in the early 1960s and was to give birth to a number of computer programs (such as Lexico3, Alceste, Hyperbase and so on), and text linguistics (Adam, 1999) plus the many developments in enunciative pragmatics that developed from the late 1970s onwards (in the wake of Benveniste, 1974; see Maingueneau, 1991), and which marked the end of structuralist hegemony by turning to the utterances as the smallest communicative units of discourse (Angermuller, 2014). From the beginning, French discourse linguists were joined by a number of historians (Guilhaumou et al., 1994), specialists in media and communication sciences (Charaudeau, 1983) and sociologists, who shared the emphasis that many French linguists, versed in the formalist and philological traditions of French letters, usually place on the 'opaque materiality' of texts. Today, with its focus on written texts, Discourse Studies in France prolongs the heritage of 'antihumanist' discourse theorists which linguists have put into discourse analytical practice.

Even though as a field Discourse Studies in the US is largely limited to small areas within sociolinguistics (Labov and Fanshel, 1977; Johnstone, 2008; Gumperz, 1982), corpus analysis (Biber et al., 1998), applied linguistics (Kramsch, 1998), and linguistic anthropology (following pioneers like Malinowski, 1923; Hymes, 1972; Duranti, 1997), discourse is well-known as a concept and a problem. Theoretically, 'discourse' is informed by the rich tradition of symbolic

interactionist and praxeological research which prolong the philosophical tradition of North American pragmatism. Symbolic interactionism, even though its name was only created after the war, draws from the work of George Herbert Mead (1967). It started with ethnographic investigations of the Chicago School and came on the scene during the 1960s and 1970s (Sacks, 1992; Cicourel, 1973; Goffman, 1981). While these theorists are better known as pioneers of the field of qualitative social research, 'discourse' in this context is often understood as a symbolically mediated turn-taking practice in an institutional setting, and it has loosely informed a number of developments in sociology, the political sciences and anthropology. With its strict empirical orientation recognizing the creative potential of human actors, interactionist discourse ideas are typical for microsociological strands in the social sciences whereas post-structuralist discourse theories, which started to arrive from France in the 1970s, have, by and large, been restricted to debates within the humanities.

Discourse Studies in the UK represents almost the entire spectrum of theoretical and analytical strands in Discourse Studies. Post-structuralist discourse theories (Laclau and Mouffe, 1985; Hall, 1980; Rose, 1996) have developed in the political sciences and sociology whereas linguistic discourse analysis has seen contributions from sociolinguistics (Sinclair and Coulthard, 1975; Coulthard, 1977; Stubbs, 1983) as well as corpus analysis (Sinclair, 2004; Baker, 2005). Discourse Studies in the UK testifies to the intellectual presence of pragmatics in philosophy and linguistics. In philosophy, pragmatics goes back to the later Wittgenstein (2003) who, with his concept of language games points to the practical dimension of language use. Through Austin's speech-act theory (Austin, 1962; Widdowson, 2007) and Grice's theory of conversational maxims (Grice, 1989), pragmatic ideas have turned the linguistic debate toward discourse (Brown and Yule, 1998; Hoey, 2001; Hyland, 2005). With its insistence on social practices, Halliday's social semiotics (Halliday, 1978; Kress and van Leeuwen, 1996) has influenced CDA (Fairclough, 1992). CDA testifies to the interest in power and inequality, which has seen similar developments elsewhere (Jäger, 2007; Reisigl and Wodak, 2009; van Dijk, 2009).

Like the UK, the German-speaking debate on discourse reflects this broad range of approaches (Angermüller, 2011; Angermuller et al., 2014b; Wrana et al., 2014a). Although German-language Discourse Studies can be viewed as a relative latecomer vis-à-vis the French and Anglo-American traditions, it is now well established across the entire social sciences and humanities. If the traditional 'German' discussion on discourse privileges holistic models which emphasize the richness of meaning-making activities in human culture, discourse is perceived as a space into which actors enter to reach an agreement (Habermas, 1985), as a stock of knowledge shared by all the members of a society (Keller, 2005) or in terms of collective symbols which represent organic social communities (Link, 1982). Post-structuralist approaches by contrast have been particularly interested in the discursive construction of subjectivity in neoliberalism. They have been characterized by their special emphasis on the articulation of the theoretical and methodological dimensions of discourse research (Herschinger, 2011; Macgilchrist, 2011; Nonhoff, 2006; Wrana, 2006). Linguistic discourse researchers have prolonged pioneering research in text linguistics (Warnke, 2007) as well as in semantics (Busse, 1987; Ziem, 2008).

It is these four countries which have coined specific recognizable 'styles' which today exist as more and less hybrid representatives in all parts of the world: the focus on decentered subjectivity in 'French' post-structuralism, the observation of turn-taking practices in symbolic interactionism from North America, the analytical focus on language in use in 'Anglo-Saxon' pragmatics, and the interpretative approaches to shared meaning and heterogeneous knowledge in the German-speaking world.

Currently, Discourse Studies testifies to a great deal of heterogeneity between the disciplinary and national fields in which it is practiced. At times, discourse is merely a fad where old questions are clad in new discourse-theoretical terms. However, discourse has also been the object of a long and systematic investigation in specialized subfields in the disciplines and has now become the object of the transdisciplinary field of Discourse Studies.

Discovery: Legal Aspects

This article is a revision of the previous edition article by S. Bundy, volume 6, pp. 3739–3743, © 2001, Elsevier Ltd.

Abstract

Discovery – the legal process for exchanging information relevant to disputed factual and legal issues in litigation – varies considerably from jurisdiction to jurisdiction. This article compares discovery under the two primary systems of justice in use in the world today: common law jurisdictions and civil law jurisdictions. The article uses the United States and England as illustrative common law jurisdictions, outlining the scope of discovery, automatic disclosures, affirmative discovery, electronic discovery, and sanctions under each system. It then contrasts those approaches to the much more limited concept of discovery attendant to civil law jurisdictions, in which the judge (rather than the parties) controls the gathering of information.

Introduction

Discovery is the legal process for exchanging information relevant to disputed factual and legal issues in litigation. While discovery can take place in both civil and criminal cases, this article will focus on the civil procedures. This article briefly outlines the purposes of pretrial discovery. It then describes the basic regimes of pretrial civil discovery in the United States and England – the two leading common law jurisdictions – and contrasts their approaches with analogous civil law institutions.

The Aims of Discovery

In common law systems, the issues in dispute are framed by the pleadings – typically a complaint presenting the plaintiff's claims and an answer presenting the defendant's defenses. There is a process for testing the legal sufficiency of the pleadings, often in the form of a motion to dismiss. There is also a process before trial for adjudicating claims as to which the facts are not disputed, often in the form of a motion for summary judgment. The idea behind such motions is that the purpose of a trial is for the fact finder – jury or judge – to hear the witness testimony and make credibility determinations. If there are no disputed material facts, there is no need for a trial and the court can adjudicate the dispute by applying the law to those undisputed facts.

Discovery is the process that bridges the pleading stage and the summary judgment or trial stage of litigation (see Herbison, 2000: pp. 1524–1525). For claims and defenses that survive early challenges, discovery is the process for exchanging relevant – or potentially relevant – information. This exchange of information during discovery has a number of purposes and potential benefits.

At the most fundamental level, discovery serves to make available the facts and information relevant to the dispute. Bringing the witnesses and documents out into the open allows the parties and the court to identify those claims – or portions of claims – as to which there is no genuine dispute of material fact, allowing for disposition without trial. It allows the parties to better assess the merits of their positions, facilitating settlement (Subrin, 2002: pp. 311–312). And barring resolution through motion or settlement, it leads to a more fair and efficient trial by focusing trial on the actually disputed issues and avoiding 'trial by ambush,' where one party springs surprise witnesses or documents on an opponent at the last minute (see Grimm and Yellin, 2013: p. 509).

In contrast, in civil law jurisdictions, discovery is not a separate step bridging the pleadings and the trial, but instead is an integral component of a judicially orchestrated search for the truth (Hazard, Jr., 1998a: p. 1019). Documents are gathered and witnesses are questioned, but all at the pleasure of the judge.

Of course, these discovery processes do not come without cost, and the escalating cost of discovery is hotly debated. Any consideration of the purposes and benefits of discovery must be balanced by recognition of the substantial monetary and time expenditures that discovery entails (Moss, 2009: p. 936). The more discovery a system allows, the greater the cost and delay of the discovery process. Views differ on the balancing of these considerations, with some seeing broad discovery as opening justice to individual plaintiffs injured by large corporations who will not voluntarily disgorge their damaging documents, and others seeing the high costs of discovery leading defendants to make substantial payments to settle even frivolous claims just to avoid even greater discovery costs (see Subrin, 2002: pp. 311–312; *Bell Atlantic*, 550 U.S. at 559).

Discovery in Common Law Jurisdictions

Discovery in common law jurisdictions is generally much more extensive than discovery in civil law jurisdictions. The United States and England are two of the lead common law jurisdictions, and there are differences in their approaches to discovery as well. This section will explain discovery in the United States and England, and the next section will consider discovery in civil law jurisdictions.

Discovery in the United States

In the United States, there are federal courts – essentially limited to claims involving federal laws and for larger claims

between citizens of different States – and State courts, with more general jurisdiction. Each State has its own rules of civil procedure, governing many procedural aspects of litigation including discovery. Some States have modeled their rules of civil procedure on the Federal Rules of Civil Procedure, but others have not. This article discusses the Federal Rules of Civil Procedure.

Fundamentally, discovery in the United States forms an integral part of the litigation process, and is more extensive than in any of the other jurisdictions considered here (Walpin, 1997: p. 560). In the United States, the pleadings are designed to put the parties on notice of the nature of the claims and defenses, rather than to provide all of the facts and evidence supporting those claims and defenses. One advantage of notice pleading is that it eliminates some of the technicalities of code or fact pleading systems, which can result in the early dismissal of claims that make small technical errors in pleading. This structure is also designed to promote access to the courts in such cases as civil rights, products liability, securities, and antitrust, in which critical evidence frequently resides in the files and minds of the defendants. In these lawsuits, it would often be very difficult, if not impossible, for the plaintiff to plead facts or evidence with particularity in the complaint, as is required in fact or code pleading jurisdictions. The consequence, though, is that it places greater emphasis on discovery to bring the facts and the parties' positions to light (Subrin, 2002: pp. 311–312). Thus, discovery in the United States is quite broad.

Scope and Limitations

Discovery in the United States is available for "nonprivileged matter that is relevant to any party's claim or defense" (Baicker-McKee: Part III, 26(b)(1)). Thus, materials that are privileged attorney–client communications or that were prepared in anticipation of litigation are shielded from discovery. The requirement that discovery be 'relevant to any party's claim or defense' normally prevents a party from propounding discovery designed to develop new claims or defenses – discovery must be targeted at claims and defenses already in the pleadings, and may not be a 'fishing expedition.' This scope may be expanded by motion, subject to the court's discretion.

In order to be discoverable, a document or piece of information needs to either be admissible at trial or reasonably likely to lead to the discovery of admissible evidence. The discovery obligations extend to documents in a party's 'possession, custody, or control,' with control generally referring to documents held by another which the party has the right or ability to obtain upon request.

The scope of this discovery is quite broad. However, the rules include some protections for overly burdensome, harassing, or otherwise onerous discovery. These procedures add the concept of 'proportionality' to discovery. Essentially, if the cost or burden of discovery outweighs its likely benefits, the court may excuse a party from responding.

The United States litigation system is an adversarial system, such that it principally relies on the parties to request the information they want in discovery. The judge's role during the pretrial process is not to seek out the truth, but rather to referee the parties' conduct during the discovery process. The parties propound discovery, respond, and interpose objections without court involvement unless one party files a motion seeking to compel compliance by an opposing party, seeking protection from discovery by an opposing party, or seeking sanctions.

Although the United States system relies primarily on affirmative discovery propounded by the parties, in 1993 the United States introduced the concept of automatic disclosures for certain categories of information – junctures in the litigation process where the parties provide information to their opponents without the need for a request. This system of automatic disclosures recognizes that there are certain categories of information that parties will want in virtually every case, such that automatic disclosure of that information is more cost-effective and speeds the process along. Other information is obtainable only upon request.

Disclosures

There are three rounds of automatic disclosures in the United States. Near the beginning of a case, the parties must disclose the witnesses and exhibits that they may use to support their claims or defenses, calculations for any damages they seek, and the existence of any insurance potentially covering the claims in the case. Note that this disclosure is only for information that the disclosing party may use – information helpful to an opponent only need be produced if requested. The second round of disclosures pertains to experts, and requires identification of testifying experts and disclosure of information about their anticipated expert opinions and the basis for those opinions. The final disclosure is the pretrial disclosure, which requires disclosure of the documents, witnesses, and deposition testimony that the disclosing party intends to or may use at trial (Baicker-McKee: Part III, 26(a)).

Affirmative Discovery

In addition to these automatic disclosures, the Federal Rules provide a variety of mechanisms for affirmative discovery requests. This is the process in the United States where a party may seek evidence that an opponent has that are helpful to the party and adverse to the opponent. Remember that the disclosures apply to information helpful to the disclosing party – affirmative discovery is the process for obtaining documents and information not required to be disclosed.

Written discovery includes interrogatories (written questions), requests to inspect documents or property, and requests for admission (requests that a party admit facts, which are then deemed established and may not be controverted at trial). Parties may also take depositions (oral, recorded examination of witnesses that may then be used at trial for impeachment or, in certain circumstances, as substantive evidence). Finally, parties may, pursuant to court order or stipulation, arrange for a plaintiff to be examined by an expert for any condition at issue in the litigation (Baicker-McKee: Part III, 30–36). The court will set a period for this affirmative discovery – typically 4 to 6 months, but often longer.

Of these devices, depositions are used in the United States to a far greater extent than in other jurisdictions, and are often the most effective manner of obtaining critical information (Herbison, 2000: pp. 1524–1525). Depositions allow a party's attorney to ask questions directly of an opposing party, without the filtering that the other party's lawyer interjects in responses

to written discovery. Depositions also allow for more, and more immediate, follow-up, and allow counsel to assess the credibility of witnesses. Given the rarity of trials in modern practice in the United States – less than 2% of cases go to trial – depositions are often the most important part of the litigation process.

This affirmative discovery process results in the greatest cost component of civil litigation in the United States and can greatly extend the duration of many litigation matters (Walpin, 1997: p. 560). Indeed, pretrial discovery is estimated to amount to about 80% of the cost of any major litigation. In particular, as explained in the next section, the explosion of electronic discovery has dramatically increased the cost and duration of discovery.

Electronic Discovery

It is well settled in United States courts that electronically stored information (often referred to as ESI) is discoverable in the same way that paper documents are. Thus, nonprivileged information relevant to any party's claim or defense is discoverable if located in an e-mail, on Facebook or Twitter, in a word processing file, in a spreadsheet, in a database, on a smartphone, on a backup tape, in browser cache, etc. Because of the proliferation of electronic data and the more casual nature of communications like e-mail or Facebook posts, electronic discovery has become the focus of discovery in many cases in United States courts, and the attention to, and cost of, electronic discovery seems to be on an upward trend. The total cost of e-discovery in the United States had grown to almost $3 billion by 2009 (Yip, 2012).

In addition to cost, electronic discovery implicates two significant concerns. First, given the volume of electronic communications and the ease with which they are disseminated, electronic documents implicate privilege concerns. Of primary concern, privileged documents are often inadvertently produced during discovery. While the rules allow a party to recall, or 'claw back,' inadvertently produced documents, the disclosure may have waived the privilege. Second, electronically stored information is easily deleted, potentially leading to sanctions for failure to preserve evidence.

Discovery Sanctions

Failure to follow the letter or the spirit of the discovery rules can lead to sanctions. These sanctions routinely involve reimbursement of the resulting cost incurred by the opposing party, but may also include excluding certain evidence, deeming certain facts admitted or established, and even in extreme cases entering a dispositive ruling against the offending party (Baicker-McKee: Part III, 37). In general, however, before seeking sanctions, a party must 'meet and confer' with the opposing party, explaining the purported violations and affording the opposing party an opportunity to correct the alleged violation. Only if the opposing party refuses to correct the violation may a party file a motion for sanctions (Willoughby et al., 2010).

An issue of increasing focus for discovery sanctions in the United States is the failure to preserve documents. The increased volume and emphasis on ESI, and the ease with which e-mails and other ESI are deleted, has resulted in significant motion practice in this area. Courts sometimes sanction attorneys as well as parties if the attorneys do not send 'litigation hold letters' instructing all the likely records custodians to preserve relevant information, and then monitor compliance with these instructions (*Zubulake*).

Cost of Discovery

Under the American System, there is a distinction between the recovery of attorney's fees and the recovery of other types of expenses (often referred to as 'costs'). Unless a statute or contract provides otherwise, parties generally bear their own attorney's fees regardless of who succeeds in the action. As discussed above, when a discovery violation has occurred, however, some of the attorney's fees can be shifted.

Costs are handled differently. During the discovery process, the party receiving a discovery request generally bears the expense of gathering responsive information, and the party making the request must pay for any copies that it requests. The rules permit the parties to ask the court to alter this default arrangement, however. Thus, if a party believes that gathering requested information is too burdensome, the party may ask the court to require the requesting party to absorb those costs – and the court would have great discretion to respond to this request. At the end of a case, if it has not settled, then the prevailing party is entitled to recover some of its costs (but not attorney's fees) from the losing party.

Importantly, the courts have deemed most of the electronic discovery expenses outside the scope of recoverable costs (Mast, 2010: p. 1844). Thus, in most cases, a prevailing party will have its vindication mitigated by its attorney's fees and its electronic discovery costs.

Discovery in England

Like the United States, England is a common law jurisdiction. Most English civil cases originate in the County Courts, with appeals moving through the High Courts, the Courts of Appeal, and then potentially to the UK Supreme Court as the court of last resort. Prior to 1999, the County Courts and the appellate courts followed different procedures. With the advent of the Civil Procedure Rules (or 'White Book') in 1999, each court system became governed by the same set of procedures (Civil Procedure Rules, Part 1.02). These rules stress the importance of balancing equality for both parties against proportionality of costs – seeking to ensure that exorbitant costs do not act as a bar to obtaining justice (Mast, 2010: Part 1.1; Vorrasi, 2004: p. 362).

Discovery in England represents a middle ground between the broad discovery in the United States and the more limited discovery in civil law jurisdictions. It still leaves a role for the parties in crafting discovery requests to opposing parties, but entails significantly more 'hands on' involvement by the judge.

Scope and Limitations

Although the United States and England are both common law jurisdictions, English discovery is considerably narrower than U.S. discovery. The scope of discovery in England is largely dictated by the type of 'track' to which the judge assigns the case: small claims track, fast track, or multitrack (Gensler, 2010: p. 708; Civil Procedure Rules, 2014: Part 26.6). The small

claims track is generally used for any dispute where the claimed amount is not more than £10 000. The court normally allocates a few hours to the resolution of these types of disputes. These cases have very limited discovery, and in fact the larger discovery rule does not even apply to cases on the small claims track. The fast track is used for claims not exceeding £25 000, and only for those cases where the judge determines that the trial will only last for a single day and where oral expert evidence at trial will be limited to one expert per party. These cases are anticipated to be heard within 30 weeks of the judge's assignment to the fast track. The multitrack designation is used for any case that does not fit into either of the other categories.

English courts generally classify documents in one of four ways: (1) documents owned by the parties upon which they intend to rely; (2) documents that are materially adverse to a party's claim or defense; (3) documents that are relevant, which may provide color to the claim and a backstory but "do not obviously support or undermine either side's case"; and (4) "train of inquiry documents," or those documents that "may lead to a train of enquiry enabling a party to advance their own case or damage that of their opponent's" (Civil Procedure Rules, 2014: Part 31.6). While American style discovery would generally encompass all four categories of documents above, the extent to which English discovery applies depends on the track to which a case is assigned, as discussed below in Section Disclosures.

Like in the United States, parties in England need not produce privileged documents or communications. Additionally, "English law has not developed a work-product doctrine but has, instead, recognized a concept of litigation privilege that covers much of the same territory. Litigation privilege and attorney-client privilege, generally referred to in England as legal advice privilege, are so closely interwoven in English law that no discussion of legal professional privilege would be complete without some reference to both" (Pike, 2006: p. 61).

Like in the United States, the parties may ask the court to expand or contract the scope of discovery. However, unlike the United States, the English system focuses much more on defined disclosures and less on affirmative discovery requests by the parties. Likewise, as the following section demonstrates, discovery in England is more concerned with the first two categories described above – documents that a party intends to use to support its claims or defenses and documents directly adverse to those claims and defenses.

Disclosures

In contrast to the limited automatic disclosures in the United States, the English system relies heavily on disclosures for most of the information exchanged in discovery. These disclosures are considerably more extensive and complex than disclosure under the United States system.

Initial information in a case in England is exchanged by a required questionnaire. While the small claims track questionnaire is more limited, the fast track and multitrack questionnaire asks parties to: explain the issues in the case; affirm that they have made the required preclaim effort to resolve their dispute and exchanged documents accordingly; provide information about their willingness to settle in the future; discuss the possibility of applying for summary judgment in the near future; disclose any agreements reached regarding discovery of electronic or paper documents; and name the experts and witnesses they plan to use (FormFinder).

After the questionnaire, in fast track and multitrack cases, the parties sometimes exchange additional information by 'Standard Disclosure.' Standard Disclosure only encompasses the first two categories of documents listed above – it "requires a party to disclose only the documents on which he relies, and the documents which adversely affect his own case, adversely affect another party's case, or support another party's case" (Civil Procedure Rules, 2014: Part 31.6). To 'disclose' a document does not necessarily mean to produce the document to an opponent, but merely means to state "whether a document exists or has existed." The search for these documents needs only be 'reasonable,' and is limited to only those documents in the party's control – meaning in its physical possession or to which it has the right to physical possession or inspection of the document (Civil Procedure Rules, 2014: Part 31.2, 31.7, 31.8).

Because Civil Procedure Rule 31 does not apply to cases on the small claims track, Standard Disclosure is not required for these claims. Rather, the court, in preparation for the hearing, will give a 'Standard Direction.' Under a Standard Direction, each party is directed to "file and serve on every other party copies of all documents (including any expert's report) on which he intends to rely at the hearing." There is no requirement to produce a list of documents, nor is there any formal inspection in advance of the hearing. The use of experts is limited, and only permitted at the discretion of the court (Civil Procedure Rules, 2014: Part 27.2, 27.4, 27.5.1).

For fast track cases, the court may, but is not required to, order the parties to make the Standard Disclosure. If the court orders a more narrow disclosure, it will specify the scope of required disclosure, which could include no disclosure whatsoever or list specific classes of documents that the parties must disclose.

Although for several years Standard Disclosure was the normal starting point for multiclaim cases, a 2013 amendment to the rules put in place a process where the parties meet at the outset of a case and then submit a report to the court. This report includes a brief description of the documents that may exist, their relevancy, their location and how they are stored (if electronic), and the estimated cost to search and retrieve the information. The judge then has a variety of discovery plan options from which to choose, and will give direction at the case management conference (Civil Procedure Rules, 2014: Part 31.5).

Affirmative Discovery

Standard Disclosure under any of the tracks does not generally extend beyond information in the first two categories above. In order to seek information under categories 3 and 4 – documents that provide back story and train of inquiry documents – a party must request Specific Disclosure under Civil Procedure Rule 31.12. The party must demonstrate that the search is 'relevant and proportionate,' and in deciding whether to grant the order, "the court will need to satisfy itself as to the relevance of the documents sought, and that they are or have been in the party's control, or at least that there is a prima facie case that these requirements will be met."

In addition to requesting Specific Disclosure of documents, parties may also seek other forms of discovery – they may ask the court to permit the taking of witness statements, draft questions to joint experts, and seek to have the other party admit facts.

As discussed above, in the disclosure stage, the parties do not provide a copy of the documents, they merely advise the other parties of the existence of disclosable documents. The party to whom a document's existence was disclosed may submit a written request to inspect the document. The disclosing party must produce it unless: it no longer controls the document; it has a right (such as legal privilege) or duty to prevent inspection; or it asserts that the burden of producing it is disproportional to the benefit (Civil Procedure Rules, 2014: Part 31.3). If a party wishes to challenge an assertion of privilege or proportionality, the party seeking the document can apply to the court and ask the court to decide if the assertion should be upheld.

Although the Civil Procedure Rules permit depositions of witnesses, due to costs, depositions are generally regarded as a tool of last resort; the rules promote the use of live witness testimony at trial or sworn statements over depositions. In lieu of depositions, the parties exchange witness statements for witnesses upon whom the parties plan to rely. This process stands in marked contrast to the process in the United States, where depositions are routinely conducted in every large or complex case.

The role of experts, as well as the discovery conducted regarding those experts, differs significantly between the United States and England. In the United States, experts are almost exclusively hired by the parties and act as advocates for the parties who hire them. In England, the rules provide that the overriding duty of an expert is to the court, not to the party who hired the expert. An English court may "direct that evidence on [a specified issue] be given by a single joint expert," and the court may also choose the means by which the expert is selected. These rules are driven by the desire to limit costs, as well as perceived expert partiality under the old system (Civil Procedure Rules, 2014: Part 35.1). Where each party has retained its own experts, the court may require the experts to work together to publish a report identifying the issues where they agree and disagree.

Beyond these procedures, there is very little affirmative discovery in the English courts.

Electronic Discovery

Civil Procedure Rule Part 31.4 defines 'documents' as "anything in which information of any description is recorded," and it is well established that e-mails, text messages, photos, voice-mails, audio recordings, databases, meta-data, and all other associated forms of electronic communications are included in the scope of Rule 31. Parties are required to discuss a discovery plan for ESI prior to the first case management conference. Similar to the American rule, as soon as litigation is anticipated, an attorney must notify the client of the obligation to preserve documentation that would be subject to disclosure.

Discovery Sanctions

Sanctions in England for violations of discovery rules can range from being denied the ability to rely on certain documents or witness testimony, to the possibility of being held in contempt of court. A party who fails to disclose an expert's report at the time specified in the case management order may be denied the ability to use the report at trial or call the expert to testify.

Cost of Discovery

In weighing the proportionality of cost, the Civil Procedure Rules require an English judge to consider the amount of money involved in the dispute, compared to the relative importance of the case, along with the complexity of the issues. These three factors are considered alongside each party's relative financial position. This cost/benefit analysis is then factored against the need to ensure both the plaintiff and defendant are given equal footing, the desire to avoid wasted resources (both time and money), and the judiciary's opportunity cost of using those resources on the dispute in question rather than on some other dispute.

At the end of a case, the 'English Rule' requires the losing party to bear the costs and attorney's fees of the prevailing party, subject to the determination by a taxing master as to what costs are recoverable (Feuerstein, 1995). This approach is designed to discourage frivolous suits by making the party bringing the suit exposed to the risk of bearing substantial costs incurred by the defendant.

Discovery in Civil Law Jurisdictions

Fundamental differences exist between the common law and civil law tradition. Unlike the common law, the civil law is found exclusively in written laws, and is not created by judges in precedential opinions (Honsel et al.: Section 23.3). Therefore, each dispute is merely a resolution for those two particular parties, decided by a civil system judge charged with applying the code to the particular facts and arriving at the result dictated by the code. The lawyer's role is also different in civil law jurisdictions: "in principle, the advocates' function is to assist the judge in fulfillment of the judicial responsibility, rather than, as in the common law," to zealously advocate for one party (Hazard, Jr., 1998a: p. 1020). The differences in these systems translate into vastly disparate approaches to discovery.

At the outset of an action, the forms of pleading differ. American law allows for 'notice pleading,' under which the complaint merely puts the defendant on notice of the nature of the claim, and relies on discovery to uncover the relevant facts (Subrin, 2002: p. 311–312). In contrast, civil law jurisdictions employ a more rigid 'fact pleading' standard, under which the complaint must include a detailed recitation of the facts, and often must include a description of supporting evidence as well (Dodson, 2010: p. 443). The parties may also attach documents favorable to their case to their pleadings (Bolt and Wheatley., 2006: p. 8). As a result, the plaintiff will already have been forced to disclose some of the facts and supporting evidence at the earliest stage of the case (Dodson, 2010: p. 443). This difference in pleading style dictates a greater need for discovery in common law jurisdictions.

After the plaintiff has filed its claim, the further exchange of facts and evidence proceeds very differently in civil jurisdictions. The judge, and not the parties' attorneys, will initiate

the production of further facts and evidence (Hazard, Jr., 1998a: p. 1020). Indeed, the judge's role to orchestrate production of evidence is seen as fundamental to the civil law tradition. In Germany, for example, it is solely the judge who may compel document production; a party has no procedural right to request a document. If a party asks the judge to request documents from another party, the judge will only grant the request if "the documents are relevant, specifically designated, and [either] … the requesting party can show a substantive right to the information … [or] the opposing party has made reference to the sought-after documents …." (Bolt and Wheatley, 2006: pp. 8–9). The German rules also provide for the judge to propound written interrogatories to the parties (as opposed to one party serving interrogatories on another in the common law systems) (Honsel et al.: Section 23.45).

American style depositions are not conducted in civil law jurisdictions, and attorneys generally have very limited interactions with witnesses in advance of the trial (Kötz, 2003: p. 63). Although the parties may propose witnesses for certain factual issues, it is the judge who decides whether the witness will be called, dictates the order in which the witnesses will be called, asks the witnesses questions, and summarizes their statements (Kötz, 2003). While the parties' attorneys do have the chance to ask questions after the judge has finished, in practice, this witness questioning is normally not extensive, and is not comparable to the American style cross-examination (Kötz, 2003).

Civil trials also proceed very differently in civil law jurisdictions. Civil law jurisdictions do not permit jury trials in civil suits – the judge acts as trier of both law and fact (Dodson, 2008: p. 141). In fact, there is often no single consolidated trial of all the issues (Hazard, Jr., 1998b: p. 1673). Instead, the civil law judge may hear presentations of facts and law at several small conferences, on different topics at each conference, until the judge decides that the case is ready for adjudication. No pretrial discovery is conducted because there is no real trial at all; the judge simply decides the case on an issue-by-issue basis as the judge sifts through facts and evidence presented at several short hearings, until such time as the judge is ready to announce the final decision (Hazard, Jr., 1998a: p. 1020).

Consistent with the role of the civil judge as the seeker of the truth, civil judges will choose and appoint experts, normally by working in conjunction with the parties. The judge will pose questions to the expert directly during the course of the hearings (Kötz, 2003: p. 64).

Thus, discovery is much more narrow in civil law jurisdictions, and is conducted in a fundamentally different manner than in common law jurisdictions. It is principally directed by the judge, searching for the truth, rather than by the parties seeking to advance one particular perspective.

Interjurisdictional Discovery

When a party in a common law jurisdiction seeks to conduct discovery in a civil law jurisdiction, or vice versa, confusion – and sometimes legal difficulties – can ensue. As one law professor has noted, "the impression of American discovery in most foreign countries is that of an alien legal regime conducting a warrantless search in someone else's domestic territory" (Hazard, Jr., 1998b: p. 1676). Since the civil law judge functions as the primary collector and sifter of facts in the courtroom, an American style discovery request sent directly to a foreign party may be seen by the tribunal as either an 'attempt to circumvent the judiciary' or a 'preemptory demand' on the judge (Hazard, Jr., 1998a: p. 1020).

American discovery laws frequently run contrary to European privacy laws (Bolt and Wheatley, 2006: p. 13). Many civil law jurisdictions, and some common law jurisdictions, have therefore enacted blocking statutes to prevent American parties from seeking American style discovery within their borders (Bolt and Wheatley, 2006).

Conclusion

The fundamental differences between common law jurisdictions and civil law jurisdictions are manifest in their approaches to discovery. In the United States, the pleadings merely frame the issues, and the facts and evidence are developed through broad discovery, conducted by the parties in an adversarial manner. Not only are documents exchanged, but parties frequently seek information by written interrogatories and by oral examination during depositions. This approach promotes access to the courts, making it more feasible for a 'David' plaintiff to sue a 'Goliath' defendant. The price tag for this access to the courts is a more costly and prolonged litigation process, and the proliferation of electronically stored information appears to be driving up the price and delay of discovery.

In contrast, in civil law jurisdictions, the pleadings advance many of the facts and evidence at the outset of a matter, reducing the need for extensive discovery. The judge then dictates the discovery the judge deems necessary to adjudicate the dispute, which is typically limited to the production of documents. The process is considerably less expensive and time consuming than in the United States, but it may impose barriers for an individual who has good cause to believe a large corporation is acting improperly but who needs evidence from the corporation to prove the case.

Discrete-State Models of Information Processing

William H Batchelder, University of California, Irvine, CA, USA

© 2015 Elsevier Ltd. All rights reserved.

Abstract

Discrete-state models for information processing tasks assume that overt responses to stimulus inputs are probabilistically determined by a small set of latent mental states. The earliest examples were in signal detection and mathematical learning theory. Later, the class of multinomial processing tree (MPT) models was developed. MPT models assume that stimulus inputs probabilistically select processing branches in a tree structure, where each branch is a possible sequence of latent cognitive acts leading to an overt response. MPT models have been developed for many information processing tasks, and their statistical theory is well developed at the class level.

Introduction

Discrete-state models for information processing (IP) tasks assume that overt responses to stimulus probes are determined by unobservable (latent) mental states. Viewed generally, IP tasks involve experimental paradigms where a subject must classify each of a set of N stimulus items, $\mathscr{S} = \{S_1, \ldots, S_N\}$, into a set of J response categories, $\mathscr{C} = \{C_1, \ldots, C_J\}$. A discrete-state model assumes that there is a small set of M latent (unobservable) cognitive states $\mathscr{L} = \{L_1, \ldots, L_M\}$, and corresponding to each of these states is a probability distribution over the response categories. Thus, the probability that a stimulus item S_i is classified into a particular response category C_j is computed by summing response probabilities over the latent states, namely,

$$\Pr(C_j|S_i) = \sum_m \Pr(C_j|L_m)\Pr(L_m|S_i) \qquad [1]$$

Despite the simplicity of Eqn [1], the special character of a discrete-state model depends on the structure of the latent states and the associated probabilistic processes.

Most IP paradigms are either detection tasks or learning tasks. In detection tasks, the subject knows the basis for a correct classification, and in learning tasks, they must acquire the basis for a correct classification from a series of learning trials. An example of a detection task is a Yes/No recognition memory paradigm with word stimuli, discussed in the next section. An example of a learning task is a paired-associate learning task discussed in the section on Markov learning models.

In the early history of IP modeling, most discrete-state models were either signal detection models or Markov learning models. The second and third main sections respectively, will describe briefly these two classes of discrete-state models. For the past 25 years, most discrete-state models fall into the class of MPT models. Section Multinomial Processing Tree Models will describe these models and their statistical inference in some detail.

Signal Detection Models

One of the earliest applications of discrete-state models was in the area of signal detection. A frequent signal detection paradigm is the Yes/No task (see Signal Detection Theory, History of). In this task, subjects are exposed to a series of items, some of which are classified as 'signal items' (S), and others are 'noise items' (N). One example is a recognition memory task where subjects first study a list of words, one at a time, and then they are given a test consisting of old studied words (signal items) and new, unstudied words (noise items, foils). The subject must classify each test word as 'Yes' (old studied word) or 'No' (foil). Other examples include auditory signal detection, where the signal items are tones that include extra energy at a particular frequency, and medical decision-making situations, where the signal items are X-rays that exhibit a particular type of tumor. In such a task, one observes the proportions of each response to each item type as a sample from the two-by-two probability matrix

$$P = \begin{bmatrix} \Pr(\text{'Yes'}|S) & \Pr(\text{'No'}|S) \\ \Pr(\text{'Yes'}|N) & \Pr(\text{'No'}|N) \end{bmatrix}. \qquad [2]$$

In standard signal detection terms, the top row of (2) exhibits, respectively, the hit and miss rates, and the bottom row, the false alarm and correct rejection rates.

Discrete-state models for the Yes/No task are characterized by the assumption that subjects set detection thresholds for the two kinds of items, and when an item is not detected, the subject responds with a guessing bias, $g \in [0, 1]$, for a 'Yes' response (Macmillan and Creelman, 2005). Such models postulate that any test item falls into one of three latent states: D_1, detected as a signal item, D_2, detected as a noise item, and D_3, not detected. The most general version of the threshold model specifies parameters for each item type to fall into each discrete state. Let d_{ij} be the probability that item type i leads to discrete state D_j, where $i = 1$ for signal items and $i = 2$ for noise items. The general threshold model specifies five nonnegative parameters, $\Theta = (d_{11}, d_{12}, d_{21}, d_{22}, g)$, where $d_{11} + d_{12} \leq 1, d_{21} + d_{22} \leq 1$. Following Eqn [1], the model can be specified by two matrices, a stimulus input matrix and a response output matrix. The stimulus matrix specifies the probabilities of getting into each of the three discrete states as a function of the item type, and the response matrix specifies the probability of a 'Yes' or 'No' response as a function of the discrete states. The stimulus matrix is given by

$$I(\Theta) = \begin{bmatrix} d_{11} & d_{12} & (1 - d_{11} - d_{12}) \\ d_{21} & d_{22} & (1 - d_{21} - d_{22}) \end{bmatrix}, \qquad [3]$$

and the response matrix by

$$R(\Theta) = \begin{bmatrix} 1 & 0 \\ 0 & 1 \\ g & 1-g \end{bmatrix}, \quad [4]$$

where the first column of the response matrix gives the probabilities of a 'Yes' response given the discrete state. It is easy to compute Eqn [2] from Eqns [3] and [4] by matrix multiplication,

$$\begin{aligned} P(\Theta) &= I(\Theta)\cdot R(\Theta) \\ &= \begin{bmatrix} d_{11}+(1-d_{11}-d_{12})g & d_{12}+(1-d_{11}-d_{12})(1-g) \\ d_{21}+(1-d_{21}-d_{22})g & d_{22}+(1-d_{21}-d_{22})(1-g) \end{bmatrix}, \end{aligned} \quad [5]$$

and Eqn [5] is easily seen to include terms in the form of Eqn [1].

The general threshold model in Eqn [5] cannot fit uniquely to a single experimental condition with multiple independent and identically distributed observations on signal and noise items because it has five parameters, and the data structure in Eqn [2] is a product binomial structure with only 2 degrees of freedom. As a consequence, there are two special cases of the model that are the ones usually employed for data from a single condition. The first is the single high-threshold (SHT) model, and the second is the double high-threshold (DHT) model. The SHT model specification sets $d_{12} = d_{21} = d_{22} = 0$, and the DHT model sets $d_{11} = d_{22} \equiv D$, and $d_{12} = d_{21} = 0$. In essence both these models assume that the detection thresholds are set sufficiently high so that detections are always accurate, and failures to detect lead to the guessing process parameterized by g. The difference between the two models is that the DHT model, but not the SHT model, allows new items to be detected as new.

Other versions of the general threshold model either require data from multiple experimental conditions, where some of the parameters are equated across some of the conditions, or are further specified to accommodate more response options. In the later case, it is commonplace in signal detection studies to require subjects to indicate confidence in their response on an ordinal scale, e.g., 6-strong 'no', 5-probable 'no',…, 1-strong 'yes'. In such cases, Luce's low threshold theory discussed in Macmillan and Creelman (2005) can be fit to data.

As a generalization, many theorists have rejected threshold models for simple two-response signal detection tasks; however, recent considerations using model selection criteria have shown that the discrete-state models continue to have support, e.g., Klauer and Kellen (2011). Furthermore, discrete-state signal detection models with threshold assumptions have been used as building blocks for other, more complex models for multidimensional stimuli. Some of these models fall into the category of MPT models discussed in a later section.

Markov Learning Models

Markov learning models refer to a variety of discrete-state models for learning and memory tasks that were especially popular in the 1960s and 1970s (see Learning: Mathematical Learning Theory, History of). Most Markov learning models were developed for concept identification paradigms or for paired-associate learning paradigms. In a concept identification paradigm, stimuli are constructed by varying values over a series of stimulus attributes, e.g., size, shape, or color. The experimenter selects a concept rule (hypothesis) that is defined by a Boolean function over the attribute values, such as 'large things' or 'red triangles.' Then subjects receive a series of learning trials, where on each trial one of the stimuli is presented, and they indicate whether or not the stimulus satisfies the concept rule. Responses are followed by feedback of the correct response category, and subjects are expected to eventually learn the concept rule over a series of such trials. In a paired-associate learning paradigm, a list of stimulus items is paired in a many–one manner with a small set of response terms. Subjects attempt to learn the stimulus–response associations over a series of study trials, where the stimulus–response pairs are presented. Learning is measured by the ability of a subject to give the correct response alternative to each stimulus item on test trials. In both types of paradigms, the responses are typically coded as errors (1) or correct responses (0); however, for a subject in a concept identification experiment there is only one sequence of coded responses, whereas in paired-associate learning there is a sequence of coded responses for every stimulus–response pairing.

Most generally, Markov learning models are a type of stochastic process defined on the entities leading to Eqn [1], namely, stimulus items, latent cognitive states, and response categories. The latent cognitive states characterize possible states of learning in a Markov chain, for example, in the case of concept identification, the states could be candidate hypotheses, and in the case of paired-association learning, each stimulus–response pairing may be in a state of learning such as an unlearned state, a short-term memory state, a forgotten state, or a long-term memory state. The effect of a study trial is to generate transitions among the latent cognitive states described dynamically by a finite state, homogeneous Markov chain. On any trial, the response to a presented stimulus item is governed by the state's conditional response probability distribution as in Eqn [1]. The starting distribution over the states, the state-to-state transition probabilities, and the state-to-response probabilities are each functions of a parameter vector, $\Theta = (\theta_1, \ldots, \theta_S)$, where each component parameter taps some latent cognitive process, e.g., selecting a possible hypotheses, forming an association, or guessing a response. Technically, most Markov learning models can be viewed as discrete-trial, discrete-state, hidden Markov chains (e.g., Smyth, 1999), because only the trial-by-trial responses are observed, and the sequence of latent states can only be inferred. The statistical inference for a Markov learning model involves estimating the parameter vector Θ from the observed response sequences. The mathematical and statistical details are presented in Wickens (1982).

One of the earliest successful Markov learning models was the so-called all-or-none model for paired-associate learning. The model is for a paired-associate learning task in which each stimulus is paired with one of a small set of response alternatives such as numbered buttons. On any test trial, each stimulus–response pairing (item) is in one of two latent states: the learned state (L) and the unlearned state (U). When a stimulus is presented on a test trial, the correct response is made if the

item is in state L, but if it is in state U there is a probability $g \in [0,1]$ that the correct response is made. This model assumes that items start in state U, and they are learned independently. On every study trial when an item is in state U, there is a probability $c \in (0,1)$ that the item makes a transition to state L, which is an absorbing state in the Markov chain. The name of the model derives from the assumption that learning either completely occurs or it completely fails to occur.

The all-or-none model is specified by a parameter $\Theta = \langle c, g \rangle$, a transition matrix

$$T = \begin{array}{c} \\ L_n \\ U_n \end{array} \begin{array}{c} \begin{array}{cc} Ln+1 & Un+1 \end{array} \\ \begin{bmatrix} 1 & 0 \\ c & 1-c \end{bmatrix} \end{array}, \qquad [6]$$

a start vector $\mathbf{S}_1 = \langle 0, 1 \rangle$, and a response vector $\mathbf{R} = \langle 1, g \rangle$. Equation [6] gives the transition probabilities for a study trial on an item, where the row corresponds to the state of the item on the nth trial before the correct response is presented for the study and the column is the state of the item after the study event. The start vector gives the probability distribution over the states before the first study event, and the response vector gives the conditional probabilities of a correct response on any trial given the state. By ordinary properties of the discrete state, homogeneous Markov chains, the probability distribution after the nth study trial is given by

$$\mathrm{S}_{n+1} = \mathrm{S}_1 \mathbf{T}^n = \langle 1 - (1-c)^n, (1-c)^n \rangle$$

and the probability of a correct response on a test trial after the nth study is given by

$$\Pr(C_{n+1}) = \mathrm{S}_{n+1} \cdot R = 1 - (1-g)(1-c)^n.$$

Many examples of Markov learning models for concept identification are found in Wickens (1982), and Markov models for paired-associate learning are reviewed in Greeno and Bjork (1973). However, Markov learning models ceased to be of major theoretical importance in learning and memory in the late 1970s, when a variety of more elaborate and detailed IP models of learning were introduced such as global memory models (see Memory Models: Quantitative), and later connectionist models (see Connectionist Models of Concept Learning) and global memory models. Nevertheless, Markov learning models have continued to serve as psychometric models for psychological measurement. For example, they have been applied to early development and to aging, where standardized paradigms provide learning sequences for different age groups that can be used to estimate age-related trends in latent storage and retrieval processes (reviewed in Batchelder and Riefer, 1999).

Multinomial Processing Tree Models

MPT models constitute a large family of discrete-state IP models for categorical data that are quite popular at the time of this writing. The MPT model family was developed and formalized, including its statistical inference, in Riefer and Batchelder (1988) and Hu and Batchelder (1994). Batchelder and Riefer (1999) and Erdfelder et al. (2009) are comprehensive review articles on the MPT models. Informally, an MPT model for an IP task assumes that a stimulus item triggers one of a number of processing sequences, each of which leads to an observable response category. There may be multiple processing sequences that result in the same response category, so knowledge of the response category does not necessarily reveal the underlying processing sequence. The remainder of this main section on MPT models will have four subsections. The first subsection will discuss the statistical specification of MPT models including an MPT representation of the DHT model discussed in the section on signal detection models. The second subsection will describe two popular MPT models, each for a different experimental paradigm. The third subsection will describe statistical inference for MPT models, and the fourth subsection will discuss application areas and modeling issues.

Specification of MPT Models

Most discrete-state IP models, including those discussed in earlier sections, can be parameterized to fit into a subclass of MPT models called binary multinomial processing tree (BMPT) models, so that subclass is specified next in detail. Basically BMPT models are a class of parametric multinomial models that specify possible probability distributions over the observable response categories in terms of model parameters. There are four aspects to a BMPT model: (1) observable categories, (2) latent parameters, (3) tree architecture, and (4) computational rules.

The first aspect consists of J response categories, $\mathscr{C} = \{C_1, \ldots, C_J\}$. The assumption is that subjects are presented with items from a particular stimulus class, and they respond to each item independently with exactly one of the J response categories. In most experimental tasks, subjects are required to respond to items from two or more stimulus classes, each with its own set of response categories. In such cases, the model specifies a BMPT model for each class.

The second aspect of a BMPT model consists of S functionally independent parameters, $\Theta = (\theta_1, \ldots, \theta_S)$, each with full range, $0 \le \theta_s \le 1$. Thus, the parameter space of a BMPT model with S parameters is the S-dimensional unit interval $[0,1]^S$. Each parameter is interpreted as the probability of the occurrence of some latent (unobservable) cognitive act, e.g., storing an item in memory, retrieving an item from storage, matching an item with a target, clustering items, making an inference, detecting a signal, discriminating between items, or guessing a response.

The third aspect of a BMPT model is its tree architecture. Each stimulus class is associated with a full binary tree that represents a set of IP sequences, each of which leads to a particular response category. A full binary tree consists of a single initial node (the root), intermediate nodes, and terminal nodes (leaves). Each nonterminal node in the tree has exactly two directed links, each leading to another node (its child) in the tree. Such a tree is usually depicted with the initial node at the top and the terminal nodes at the bottom. **Figure 1** presents the DHT model described earlier in Eqn [5] in the form of a BMPT model with two full binary trees, one for the class of old items and the other for the class of new items. Both trees have two internal nodes, three terminal nodes, and four links. Each branch (sequence of links) from the initial node to a terminal node corresponds to a possible IP sequence leading to a response category as described next.

Figure 1 A BMPT representation of the DHT model in terms of a tree for old and a tree for new items. D is the detection parameter and g is the guessing parameter.

The specification of a BMPT involves assigning a response category to each terminal node, and a parameter, $\theta_s \in \Theta$, or a number, $x \in (0, 1)$, to each nonterminal node. If a particular parameter θ_s is assigned to a nonterminal node, then the left link from that node corresponds to the success, with probability θ_s, and the right link the failure, with probability $(1 - \theta_s)$, of the corresponding cognitive act represented by the parameter. The nodes with number assignments work similarly, where x is the probability of taking the left link and $(1-x)$ is the probability of taking the right link. For example, at the initial node at the top of the left tree in Figure 1, the parameter D is assigned, and the effect of this is to associate probability D with the left link and $(1-D)$ with the right link, as depicted in the figure. Finally, each terminal node corresponds to one of the J categories. Note that a particular category or parameter may appear several times in a BMPT tree, for example, in the left tree of Figure 1, the 'Yes' category appears twice because for the DHT model there are two different processing sequences that can lead to a 'Yes' response.

The computational component of any BMPT model provides the probabilities of each observable response category as the sum of the branch probabilities leading to that category. Branch probabilities are computed as products of link probabilities and have a special form. Let B_{jk} be the kth branch in a tree leading to category C_j, then

$$\Pr(B_{jk}|\Theta) = c_{jk} \prod_{s=1}^{S} \theta_s^{a_{jk,s}} (1 - \theta_s)^{b_{jk,s}} \qquad [7]$$

where c_{jk} is the product of the numbers associated with the links of B_{jk} or set to one if there are no numerical links on branch B_{jk}, and $a_{jk,s}$ and $b_{jk,s}$ are, respectively, the number of links on B_{jk} associated with θ_s and $(1-\theta_s)$. Since each branch ends in a particular category, the category probabilities, $p_j(\Theta)$, are sums of branch probabilities,

$$p_j(\Theta) = \sum_{k=1}^{I_j} \Pr(B_{jk}|\Theta) \qquad [8]$$

where I_j is the number of branches leading to category C_j. Given this structure, it is easy to show that

$$\forall \Theta \in [0, 1]^S, \;\; p_j(\Theta) \in [0, 1], \;\; \sum_{j=1}^{J} p_j(\Theta) = 1$$

Note that in Figure 1, there are two branches in the left tree that lead to a 'Yes' response. From Eqn [7], the left most one can be written as $\Pr[B_{\gamma,1}|(D,g)] = 1 \cdot D^1 (1-D)^0 g^0 (1-g)^0$, and the second one can be written as $\Pr[B_{\gamma,2}|(D,g)] = 1 \cdot D^0 (1-D)^1 g^1 (1-g)^0$. Putting these together using Eqn [8] yields $\Pr(\text{'Yes'}|\text{Old}) = D + (1-D)g$, and this is the same probability as the hit rate in the upper left term in the matrix in Eqn [5] for the DHT model.

As in Figure 1, most models are specified for situations where subjects respond to items from several classes, each with its own BMPT model. In such cases, any given parameter can appear in several trees. The DHT model in Figure 1 has two trees, and the parameters D and g appear in both. Each item class has two response categories, and a 'Yes' response to an old item is not the same category as a 'Yes' response to a new item.

The class of MPT models also includes ones where nonterminal nodes of the tree can have more than two links, each corresponding to a different processing outcome at that node. These MPT models are called multilink MPT models, and Figure 3 (described later) is an example of such a model. Hu and Batchelder (1994) specify the class of general processing tree (GPT) models to include multilink MPT models. It is a statistically useful fact that every multilink MPT model can be reparameterized into a statistically equivalent BMPT model, where statistically equivalence means that both models entail exactly the same set of probability distributions over the response category systems.

Purdy and Batchelder (2009) provide an alternative and efficient specification of BMPT models as strings in a context-free language. The specification capitalizes on the recursive character of the tree structure of BMPT models. For example, given any two BMPT models, one can join them into a single BMPT model by specifying a new initial root node with links to the two root nodes of the two models, and by the same logic one can decompose a BMPT model recursively in terms of sub-BMPT models. Similarly, one can specify the response category probabilities recursively in terms of the category response probabilities of the submodels. The context-free language in Purdy and Batchelder (2009) consists of a collection of strings, each of which corresponds to (codes) a particular BMPT model. In fact, the entire collection of strings is in one-to-one correspondence with the collection of BMPT models that can be specified as described in this subsection. These strings provide an efficient way to code

Figure 2 A BMPT representation of the pair-clustering model in terms of a tree for clusterable pairs and a tree for singleton items.

Figure 3 An MPT model representation of the source-monitoring model for three sources.

BMPT models for computation, and they have begun to be seen in statistical inference packages.

Examples of MPT Models

In this subsection, two popular examples of MPT models will be presented. One of the first published MPT models was the pair-clustering model. The data for the model involves a specially designed free recall task, where subjects study a list of words, one at a time, and then at a later time try to recall as many list words as they can in any order. The list of words contains two classes of items: semantically clusterable word pairs, e.g., car and train or daisy and rose, and singleton words. The word pairs are classified into four response categories: (C_1) both items recalled successively, (C_2) both words recalled but not successively, (C_3) only one of the two words recalled, (C_4) neither word recalled. The singleton words are classified into two response categories: (E_1) recalled and (E_2) not recalled. The model is presented in Figure 2.

The pair-clustering model specifies three parameters, each designed to measure a different cognitive act: (1) a storage parameter c representing the probability that a word pair is clustered and stored in memory, (2) a retrieval parameter r representing the conditional probability that a clustered word pair is recalled from memory, and (3) a parameter u representing the probability that an unclustered word is both stored in memory and retrieved. Just as in Figure 1, the pair-clustering model has two trees for the two classes of stimulus items. The assignment of categories to branches in the tree for pairs is based on two approximations: (1) a subject will recall the two words in a pair sequentially if and only if they are stored as a cluster and the cluster is retrieved, namely, $\Pr(C_1|\Theta) = c \cdot r$; (2) all nonclustered items, including singleton items, are stored and retrieved independently, with probability u. Note that there are two branches in the left tree that lead to category C_3 and two that lead to C_4. In addition, note that the parameter u appears three times in the tree for pairs and once in the tree for singletons.

The model is designed to separately measure memory storage capacity and memory retrieval capacity in humans. This is important for studying the bases of memory deficits in special populations because the percentage of correct recalls confounds these two latent processes. Batchelder and Riefer (1999) and Erdfelder et al. (2009) provide many references to the origin, statistical inference, and applications of the pair-clustering model.

Another popular area for MPT modeling is a source-monitoring task. Such a task is an extension of a recognition memory task discussed earlier, where the items on the study list come from different classes defined by their presentation source, e.g., different speakers, different sensory modalities, or from different spatial locations. In the test phase, subjects must decide if an item is old or new, and in addition, they must identify the presentation source of old items. Figure 3 provides a general MPT model for a three-source experiment.

The general source monitoring model in Figure 3 has trees for each of the three classes of presentation sources for the old items (A, B, or C) and a tree for new items, and across all four

trees there are 29 processing branches. Each of the four trees is a multilink MPT model because the internal nodes near the bottom of the trees have three links rather than two as required for BMPT models. The model has 14 nonnegative parameters: four 'detection parameters' ($D \leq 1$), three 'discrimination parameters' ($d \leq 1$), and seven other parameters for guessing processes. However, the actual number of independent parameters is 12 because $a_3 = (1 - a_1 - a_2)$, $g_3 = (1 - g_1 - g_2)$. Each of the four trees has a detection parameter, D, associated with its initial node that gives the probability of correctly detecting if an item is old or new. On the three trees for old items, on the detection (D) link is a discrimination parameter, d, for the probability that the source of the old item is correctly discriminated. Successful detections and discriminations lead to correct responses to items; however, failures to detect, with probability ($1-D$), and failures to discriminate, with probability ($1-d$), lead to guessing processes. Of the guessing parameters, b is the probability that a nondetected item is biased into one of the old source categories, and the parameters a_i and g_i, respectively, are the probabilities of guessing particular sources, for nondiscriminated old items and nondetected items.

Special cases of the source-monitoring model in **Figure 3** have been used in a variety of research settings including illusory correlations, face recognition, social categorization, and a variety of clinical settings involving special populations of subjects. The advantage of the model is that it can suggest whether or not the locus of memory failures is in old/new item detection or in the ability to discriminate the presentation source of detected items. Batchelder and Riefer (1999) and Erdfelder et al. (2009) provide many references to the origin, statistical inference, and applications of MPT models for source monitoring.

Statistical Inference for MPT Models

It is a consequence of the computational rules for an MPT model that if the category counts in a particular class of stimulus items are obtained as independent and identically distributed observations, then the MPT model becomes a specially parameterized multinomial model with probability distribution

$$\Pr(< N_1, \ldots, N_J > |\Theta) = N! \prod_{j=1}^{J} \frac{p_j(\Theta)^{N_j}}{N_j!} \qquad [9]$$

where N_j is the number of counts in category C_j and $N = \sum N_j$. In the case of multiple classes of stimulus items, if the responses to all the items are independent, Eqn [9] just becomes a product of multinomials, one for each item class. This marks such models technically as parameterized product multinomial models. For example, for the DHT model of **Figure 1**, the probability distribution for the parameterized product binomial model is given by

$$\begin{aligned}\Pr[\langle N_{y1}, N_{n1}\rangle, \langle N_{y2}, N_{n2}\rangle | (D, g)] \\ = N_1! \frac{[D + (1-D)g]^{N_{y1}}}{N_{y1}!} \cdot \frac{[(1-D)(1-g)]^{N_{n1}}}{N_{n1}!} \\ \bullet N_2! \frac{[(1-D)g]^{N_{y2}}}{N_{y2}!} \cdot \frac{[(D + (1-D)(1-g)]^{N_{n2}}}{N_{n2}!},\end{aligned}$$

where $N_1 = N_{1y} + N_{1n}$ and $N_2 = N_{2y} + N_{2n}$.

Under the assumptions leading to Eqn [9], Hu and Batchelder (1994) provide classical (frequentist) methods for statistical inference for the entire class of BMPT models. The key to the inference is based on a special application of the expectation–maximization (EM) algorithm, a frequent data augmentation algorithm used in classical statistical inference. Note from Eqn [9] that there may be several branches that lead to the same category, so knowing the category counts does not directly reveal the frequency of times that each branch in the BMPT tree is traversed. The EM algorithm treats these branch frequencies as 'missing data'. Let N_{jk} be the frequency out of N_j counts of the occurrence of branch k terminating in category j, where $1 \leq k \leq I_j$, $1 \leq j \leq J$, and I_j is the number of branches ending in category C_j. Suppose the N_{jk} are known, then it is easy to see that the maximum likelihood estimators of the θ_s are given by

$$\hat{\theta}_s = \frac{\sum_{j=1}^{J} \sum_{k=1}^{I_j} a_{jk,s} N_{jk}}{\sum_{j=1}^{J} \sum_{k=1}^{I_j} (a_{jk,s} + b_{jk,s}) N_{jk}}, \qquad [10]$$

where the terms in Eqn [10] are defined in Eqn [7]. Thus, the maximization step of the EM algorithm yields a closed form expression.

There is a software package in Hu and Phillips (1999) based on the statistical theory in Hu and Batchelder (1994) that enables a researcher to design an MPT model graphically; load in the data; obtain point estimates, confidence intervals, and goodness-of-fit measures; do hypothesis testing within and between subject groups; and run Monte Carlo simulations with or without beta-distributed hyperparameters. There are several other general-purpose approaches to inference for MPT models that have appeared that satisfy the sampling assumptions leading to Eqn [9] and its extension to product multinomials, for example, population parameter mapping (Chechile, 1998) and other examples that are discussed in Erdfelder et al. (2009).

In the past decade, users of MPT models have begun to recognize that most categorical data sets in cognitive psychology violate the assumption behind Eqn [9] that the category counts are independent and identically distributed over the response categories. Violations occur when there are individual parameter differences among subjects and/or items. Smith and Batchelder (2008) provide model-free, nonparametric tests of heterogeneity in subjects and/or items for categorical data, and several recent papers reviewed in Erdfelder (2009) have provided Bayesian inference for MPT models that can handle such heterogeneities. It is expected that future applications of MPT models will increasingly utilize Bayesian inference to handle heterogeneity.

Application Areas and Modeling Issues

Batchelder and Riefer (1999) describe 30 MPT models for different experimental paradigms, and a decade later Erdfelder et al. (2009) in the lead article to a special issue of *Zeitschrift für Psychologie* on MPT modeling, describe 70 MPT models and variants in over 20 research areas. Many of these models are in subareas of human memory such as the models in **Figures 1–3**. MPT models have also been developed for other areas of human memory including eyewitness memory, hindsight bias,

process dissociation, prospective memory, and serial recall. There are MPT models in several areas of human reasoning, including propositional and syllogistic reasoning. In the area of perception, there are MPT models for object and letter recognition, speech recognition, and selective attention. In addition, there are MPT models for several experimental situations in the area of social psychology, e.g., stereotype formation, social categorization, and illusory correlation.

One of the main applications of MPT models is to measure cognitive capacities in special populations by estimating and comparing relevant model parameters. Batchelder (1998) examines the differences between using MPT models to understand experimental tasks and using them for psychological assessment. Erdfelder et al. (2009) describe MPT models that have also been used in a variety of assessment tasks such as discovering the basis of cognitive deficits in aging and clinical studies, detecting consensus in ethnographic studies, and implicit attitude measurement in social settings. The use of an MPT model for measurement requires that the cognitive meanings of the parameters are valid, namely, that it taps the probability of the cognitive act that it is designed to represent. Validity is not decided by the ability of the model to fit data, but instead it must be decided by specially constructed experiments, where specific model parameters are shown to be selectively influenced by relevant psychological variables, and unaffected by others. Consequently, almost all published articles advancing a new MPT model presents a series of experiments that support the connection of each model parameter with the underlying cognitive act that it is designed to measure.

The family of MPT models stands in contrast to most other IP models in that the latter assume much more complex cognitive architecture, more elaborate underlying processes, and in particular, continuous type variables that determine the output. In fact, many theorists view discrete-state models as theoretically impoverished. Indeed, this view is common in the signal detection literature, e.g., Macmillan and Creelman (2005), as well as in other areas of cognition, e.g., Mulder et al. (1995). In practice, however, MPT models have been most useful as simple, approximate models to measure underlying cognitive processes, in particular experimental paradigms, rather than providing a deep understanding of cognitive processes across a wide range of phenomena. In this sense, their applications led Batchelder and Riefer (1999) to coin the term cognitive psychometrics to cover the use of simple cognitive models, such as MPT models, for psychometric purposes.

Discrimination and the Law

Deborah C Malamud, New York University Law School, New York, NY, USA

Abstract

This article focuses on the development of antidiscrimination law in the United States at the federal level. It is concerned primarily with employment law and discriminatory practices involving race and gender. Other areas of US law are also considered (e.g., school desegregation) before briefly surveying international developments. The role of social science in antidiscrimination legal practice is stressed.

The Oxford Dictionary defines discrimination as 'the perceiving, noting, or making a distinction or difference between things.' As modified by descriptors such as 'invidious,' the term 'discrimination' refers to the making of distinctions that ought not to be made. When the distinction is inappropriate, because it treats differently those individuals, entities, or practices that are entitled by law to equal treatment, 'discrimination' takes on its legal meaning.

Contemporary antidiscrimination law is predominantly (or at least most controversially) concerned with distinctions drawn (or, in some cases, inappropriately *not* drawn) on the basis of socially defined personal attributes that have been and remain the bases for adverse treatment (such as race, gender, national origin, religion, disability, and sexual orientation). The legal concept of discrimination is not limited in its historical origins to group-based distinctions of this sort. As a concept in American constitutional rhetoric and law, the term also designates protectionist distinctions between states and countries engaged in interstate and foreign commerce. For purposes of this article, however, our focus shall be on 'discrimination' of the intergroup sort, in part because it is that form of discrimination that has most interested the social scientific community.

The development of any nation's antidiscrimination law is deeply dependent upon its own history and culture. In the field of race and ethnicity, the need for legal redress for race discrimination arises out of variable histories of immigration and its selective suppression, slavery and indentured labor, colonialism, and genocide. Social movements calling for legal and social change are culturally specific as well, although influenced by past experiences elsewhere in the world. Movements to identify and redress gender discrimination are also shaped by local settings. This is true not merely because the degree to which gender takes center stage depends in part upon whether and how the stage must be shared with the issue of race, but also because the variable social situation of women has much to do with how women will conceptualize their own equality and the spheres of activity in which they will press their legal claims. This article will focus on efforts by the United States at the federal level, but will conclude with a discussion of leading issues from several other countries.

Federal Antidiscrimination Law in the United States

Federal antidiscrimination efforts reach a wide array of social and legal arenas. Some of the most important of these are education, employment, voting, public and private housing, public accommodations (e.g., transportation), bank lending, government contracting, marriage and parenting, and the administration of criminal justice.

In light of the American history of slavery, civil war, failed post-civil war reconstruction of the South, and the mid-twentieth-century civil rights movement aimed at ending the pervasive segregation and oppression of African-Americans, race has been the most frequent starting point for American antidiscrimination law. The Fourteenth Amendment of the Constitution of the United States, itself a product of the Civil War experience, contains an Equal Protection Clause that serves as the primary source of federal constitutional antidiscrimination doctrine. Federal equal protection analysis generally assigns different 'levels of scrutiny' to different types of discriminatory classifications. For example, race discrimination is subject to 'strict scrutiny'; gender discrimination to 'intermediate scrutiny'; and age discrimination to 'rationality review,' the same level of review that is given to ordinary economic legislation. For a general survey, see Yoshino (2011). Governmental classifications rarely survive strict scrutiny and are rarely struck down under rationality review, although there are important exceptions that will be discussed below. The tiered structure of levels of scrutiny was long criticized by US Supreme Court Justices Stevens and Marshall (see, e.g., *Craig v. Boren, 429 U.S. 190, 211 (1976) (Stevens, J., concurring) and Dandridge v. Williams, 397 U.S. 471, 520–521 (1970) (Marshall, J., dissenting)*). Those critiques have contemporary echoes in the Court's gay-marriage jurisprudence, in which the Court is unclear as to how (if at all) it is using traditional tiered scrutiny (see *United States v. Windsor, 133 S.Ct. 2675 (2013)*; see also *United States v. Windsor, 133 S.Ct. 2675 (2013) at 2706–2707 (Scalia, J., dissenting)*).

Much of the federal antidiscrimination effort in the United States has been made under the auspices of antidiscrimination statutes. The first major federal antidiscrimination statute, the Civil Rights Act of 1964, was stimulated by the violent resistance by the South to court-ordered racial desegregation and to the 1960s civil rights movement. As interpreted by the Supreme Court, the Fourteenth Amendment does not reach discrimination by purely private parties, *see The Civil Rights Cases, 109 U.S. 3 (1883)*, and it requires proof of discriminatory intent, *see Washington v. Davis, 426 U.S. 229 (1976)*. So long as federal legislation is enacted pursuant to some other source of Congressional power (e.g., the Commerce Power), however, Congress is free to fill these gaps. Congress has also used legislation to create administrative agencies to participate in the

 http://dx.doi.org/10.1016/B978-0-08-097086-8.86023-7

work of antidiscrimination enforcement (for example, the Equal Employment Opportunity Commission in the field of employment discrimination) or to provide novel remedial mechanisms (for example, the preclearance provisions of Section 5 of the Voting Rights Act of 1965, the reauthorization of which was struck down by the Supreme Court in *Shelby County v. Holder, 133 S.Ct. 2612 (2013)*).

The American law of discrimination starts with high-sounding commitments in seminal statutes or Supreme Court opinions, but its development rapidly takes the form of the elaboration of highly specific structures of proof for dealing with discrimination claims arising under the various sources of law and in the various areas of social practice surveyed above. One result is that antidiscrimination law has developed a number of distinct specialties, each concerned with a separate jurisprudence of discrimination in its own field. Another result is that, in American antidiscrimination law, the devil is in the details. By shaping proof structures, and by applying civil procedure and evidence rules to discrimination cases, courts shape the likelihood that plaintiffs will succeed in their claims (Albiston, 1999; Bennett, 2012).

Employment

The leading federal antidiscrimination statute in the employment field, Title VII of the Civil Rights Act of 1964 (known as 'Title VII'), prohibits discrimination on the basis of race, color, sex (including pregnancy, thanks to the Pregnancy Discrimination Act of 1978), religion, and national origin. Although feminist activists lobbied for the inclusion of sex discrimination, the statute as originally proposed left sex discrimination out. It was included through an amendment proposed by a congressional opponent of the statute, whose confidence that including sex would block passage of the statute proved misplaced (Kanowitz, 1968). Once enacted, however, the prohibition of sex discrimination has been a robust and creative aspect of statutory enforcement. For example, the law of discriminatory harassment was first articulated in race discrimination cases but experienced its full legal development in the gender field.

Employment discrimination on the basis of age and disability were subsequently addressed in the Age Discrimination in Employment Act (1967) and Americans with Disabilities Act (1993) (significantly amended by the Americans With Disabilities Act Amendment Act of 2008). When Congress enacts antidiscrimination legislation on behalf of groups that do not receive 'strict scrutiny' under constitutional law, there is some tendency for the Supreme Court to be less plaintiff-friendly in its statutory interpretation – leading, in some cases, to Congressional pushback through statutory amendment (Hart, 2006). Not all groups have met with success in Congress. For example, Congress has yet to enact the long-proposed Employment Non-Discrimination Act (ENDA), which would bar employment discrimination on the basis of sexual orientation. There is debate as to whether the increasingly successful movement in support of same-sex marriage has slowed the progress toward the passage of ENDA. Compare Klarman, 2012 with Burke, 2013.

Years of development in the courts have generated several basic 'proof structures' that are used to prove discrimination under Title VII, and they are often borrowed for purposes of other antidiscrimination statutes: 'individual disparate treatment' (divided between 'pretext' and 'mixed motive' frameworks), 'harassment,' 'failure to accommodate,' 'pattern and practice,' and 'disparate impact.' (The Civil Rights Act of 1991 codified the 'disparate impact' and 'mixed motive' approaches for purposes of Title VII.) The 'individual disparate treatment' and 'pattern and practice' proof structures turn upon proof of the employer's discriminatory intent. The disparate impact proof structure does not; it relies instead upon proof of discriminatory effects of racially neutral practices, and upon the failure of the employer to prove the 'business necessity' of those practices.

In the 'individual disparate treatment' case, intent is an inference drawn by a fact finder (judge or jury) from a variety of types of circumstantial evidence aimed at refuting the possible nondiscriminatory reasons for an adverse employment action. While this sounds relatively straightforward, decades of Supreme Court cases have failed to achieve clarity, both as to the requirements for getting to trial in a 'pretext' case and as to the relationship between the 'pretext' and 'mixed motive' approaches (see Sperino, 2011). In addition, these cases (like all cases under the federal employment discrimination laws) are adjudicated not by specialized agencies or labor courts, but by generalist federal trial courts that are predisposed to undervalue them, finding creative ways to use procedural and evidentiary rulings to dismiss the cases without trial (see Bennett, 2012; Gertner, 2012). Increasingly, the Supreme Court has embraced the use of private arbitration to resolve individual employment discrimination claims, see *14 Penn Plaza LLC v. Pyett, 556 U.S. 247 (2009)*.

Most harassment cases involve proof that an employer has created a 'hostile environment' because of the plaintiff's sex, race, or other protected classification. In order for the employer to be held liable for the hostile environment, the plaintiff must also satisfy a set of requirements (derived from the common law of agency) that the Supreme Court created in order to incentivize employers to create, and employees to utilize, internal compliance processes. See *Burlington Industries, Inc. v. Ellerth, 524 U.S. 742 (1998); Faragher v. City of Boca Raton, 524 U.S. 775 (1998)*.

Limited within Title VII to religion cases is the duty to accommodate: an employer is deemed to have discriminated on the basis of religion if it fails to afford reasonable accommodation to a plaintiff's religious beliefs or practices, so long as doing so does not create undue hardship. Because the Supreme Court has found this statutory accommodation requirement to be in tension with the Establishment Clause of the First Amendment of the Constitution, it has essentially held that 'undue hardship' is present whenever a requested accommodation causes more than de minimis harm to the employer or to coworkers. *See Trans World Airlines, Inc. v. Hardison, 432 U.S. 63 (1977)*.

In the typical 'pattern or practice' cases, plaintiffs (most often a group of plaintiffs using the procedural mechanism of the class action) rely primarily on labor market analysis and statistical evidence to create an inference of intentional discrimination. In some cases, plaintiffs bolster their claims by the use of 'social framework' evidence, i.e., social scientific testimony aimed at demonstrating that the structures of the

work environment foster intentionally discriminatory decision-making (see Fiske and Borgida, 2013; Hart and Secunda, 2009). Claims are generally further supported through evidence of individual instances of intentional discrimination on the 'pretext' model. In a procedural decision that has substantive implications for Title VII, some members of the Supreme Court have signaled discomfort with finding a 'pattern or practice' of discrimination in a large entity absent proof of a centralized policy of discrimination. *Wal-Mart Stores Inc. v. Dukes, 131 S. Ct. 2541 (2011)*. Part of the Court's concern is the same as that which shapes the Court's hostile-environment harassment jurisprudence: i.e., those employers whose official policies prohibit discrimination ought not to be held liable when their subordinates disobey those policies (Green, 2011).

In a 'disparate impact' case, a plaintiff (or, more frequently, a plaintiff class) challenges a facially neutral employment practice (for example, a test) on the grounds of its disparate adverse effects on members of his or her group. So, for example, in the case of *Griggs v. Duke Power Co*. (401 US 424 [1971]), markedly lower proportions of blacks and Latinos than whites in the relevant labor market passed standardized aptitude tests and had high school diplomas, leading to diminished access to preferred jobs in the employer's workforce. Absent a showing of 'business necessity' or 'job relatedness,' the Supreme Court held, employers could not use tests and other hiring criteria that placed 'arbitrary headwinds' in the way of the progress of traditionally excluded groups. As in the case of 'pattern and practice' cases, disparate impact cases turn on social scientific expert testimony: economists (labor market analysis), psychologists (psychometric analysis), and sometimes sociologists (social framework analysis) play a crucial role.

Even after Congress passed clarificatory legislation in 1991, elements of the disparate impact proof structure remain uncertain. Because these cases involve comparison-group definitions, questions are raised in every case as to whether the reference group should be the employer's existing labor force, the applicant pool, or some other definition of the relevant labor market. The Equal Employment Opportunity Commission's standard for showing disparity has been criticized for failing to comport with social scientific definitions of statistical significance (Meier et al., 1984). The precise conceptual content of the phrases 'business necessity' and 'job relatedness' is still subject to doubt, particularly when disparate impact analysis is used to challenge employment practices other than paper-and-pencil tests (where 'job relatedness' has long been tested through psychometric techniques of test validation).

The disparate impact cause of action is available not only for objective tests (e.g., paper-and-pencil tests, physical skills tests), but also for subjective hiring practices (*Watson v. Fort Worth Bank & Trust, 487 U.S. 977 (1988)*). However, in a procedural ruling under the federal 'class action' rules, the Supreme Court has cast doubt on whether it will accept 'a "policy" of allowing discretion by local supervisors over employment matters' to serve as the basis for a disparate impact claim (*Wal-Mart Stores Inc. v. Dukes, 131 S. Ct. 2541, 2554-55 (2011)*; see Pedersen, 2012.). The Supreme Court has also restricted employers' capacity to use race-conscious measures to avoid potential disparate impact liability for tests with a demonstrable disparate impact. That option is available only if the employer has a 'strong basis in evidence' that its test does not meet the 'business necessity' standard (*Ricci v. DeStefano, 557 U.S. 557 (2009)*).

One area in which Title VII law has been relatively stable is the law of affirmative action. Under *United Steelworkers of America v. Weber* (442 US 193[1979]), employers are permitted to use affirmative action (if it is consistent with standards laid out in that opinion), and the Supreme Court reiterated more recently that the employer does not need to prove that its own prior policies were discriminatory in order to do so (*Johnson v. Transportation Agency of Santa Clara County*, 480 US 616 [1987]). The debate among the justices in these cases was open and virulent, and yet affirmative action in employment has not provoked recent challenge (in contrast to the status of affirmative action under the constitution, discussed below). There is, however, a mismatch between current social practice and the Supreme Court's past opinions. The Supreme Court has never held that the desire for greater diversity is a permissible basis for affirmative action under Title VII; despite that fact, diversity is the major stated justification for many employer affirmative action programs (see, e.g., Skrentny, 2013; Estlund, 2005). In addition, the Court's decision in the *Ricci* case is in some tension with its affirmative action jurisprudence (Shin and Gulati, 2011).

Cases decided under Title VII have long served as the model for developments in other fields of federal statutory employment discrimination law, but that tendency has its limits. Ironically, when Congress rejected a set of conservative Supreme Court decisions in the Civil Rights Act of 1991, it provided the Supreme Court with a new basis in statutory text for confining the 'mixed motive' cause of action to the core provisions of Title VII. (*See Gross v. FBL Financial Services, Inc., 557 U.S. 167 (2009); University of Texas Southwestern Medical Center v. Nassar, 133 S.Ct. 2517 (2013)*.) Fortunately for the disabled, one arena in which the Title VII model has not been followed is disability rights, where, especially after the passage of the Americans with Disabilities Amendments Act of 2008, disabled individuals benefit from an accommodation requirement that is far more robust than that available under Title VII's religion provisions.

The example of American employment discrimination law shows that the true state of antidiscrimination law cannot be assessed merely by looking at the written laws themselves. One must also be aware of how the statutes are being interpreted by courts, relevant administrative agencies, and even private arbitrators; of how generally applicable procedural and evidentiary rules are used in discrimination cases; of the expense of litigation; and of the practical availability of experts with necessary skills and experience. One must also have a sense of trajectory (is the law becoming more or less friendly to plaintiffs over time?) and of symmetry (are similar laws being interpreted in similar or dissimilar ways?).

Other Areas of American Law

In considering proof structures outside the employment discrimination field, a key factor is the unavailability of the disparate impact cause of action in constitutional cases arising under the Fourteenth Amendment (*Washington v. Davis*, 26 US

229 [1976]). Although *Washington v. Davis* was in fact an employment-testing case, the Court's decision was likely motivated by the wide range of government programs that might be subject to challenge under the Constitution.

Because of the lack of the disparate impact route, showing discriminatory intent is the key to constitutional antidiscrimination litigation. In primary- and secondary-school desegregation litigation, close judicial scrutiny was triggered in years past by findings that boards of education were operating their schools in an intentionally discriminatory fashion. Courts retained jurisdiction to administer complex court-ordered desegregation plans, often for decades. Until such time as the districts are declared 'unitary' by the presiding court, practices that were not themselves intentionally discriminatory could be challenged as perpetuating the effects of past intentional discrimination. In recent years, however, the trend has been for courts to conclude that the school districts under their jurisdiction have achieved 'unitary' status and that any continuing inequalities within the system no longer bear an organic connection to the district's past history of intentional discrimination (Orfield and Eaton, 1996). The Supreme Court has held that once a school district achieves 'unitary' status, it may only use race-conscious remedies if they satisfy 'strict scrutiny' – and it insists that 'unitary' districts may never use race in the assignment of individual pupils to particular classrooms or schools.

In higher education, affirmative action has been the focus of major political and judicial attention. The Supreme Court affirmed the constitutionality of the use of race-based affirmative action to achieve diversity in higher education in *Grutter v. Bollinger, 539 U.S. 306 (2003)*. However, 10 years later the Court stressed in *Fisher v. University of Texas at Austin, 133 S. Ct. 2411 (2013)*, that, under strict scrutiny, universities must prove that race-neutral alternatives (e.g., affirmative action based on socioeconomic class) are unavailable. Furthermore, in *Schuette v. Coalition to Defend Affirmative Action, 134 S.Ct. 1623 (2014)*, the Court upheld the power of states to enact state constitutional amendments that deny public universities the discretion to use race-conscious affirmative action.

Criminal justice in the United States has a significant racial dimension too, one that contributes to the gap in perception of the fairness of the system between blacks and whites. Some important efforts to redress racism in criminal law enforcement have met with failure, in part because of the difficulty of persuading courts of discriminatory intent through statistical evidence. For example, in *McCleskey v. Kemp* (481 US 279 [1987]), the Court rejected the claim, based on extensive statistical evidence, that the death penalty as practiced by state governments is unconstitutionally discriminatory (Baldus et al., 1983). Racial disparities in criminal law enforcement have led to scholarly and popular critiques of modern criminal justice as a current instantiation of American racial apartheid: "the new Jim Crow" (Alexander, 2012; for a response see Forman, 2012).

"In the field of voting rights, the Supreme Court has made it more difficult for voters to challenge allegedly discriminatory voting practices. Under the preclearance provision of the Voting Rights Act of 1965, proof of discriminatory intent was not required for such challenges if they were brought against certain designated jurisdictions with a history of past intentional voting discrimination. The Supreme Court held Congress' reauthorization of that provision unconstitutional in *Shelby County v. Holder, 133 S. Ct. 2612 (2013)*."

The Role of Social Science in American Antidiscrimination Legal Practice

As should be apparent from the above survey of American antidiscrimination practice, social science has a crucial role to play in proving discrimination. Social science has also been an important reality check, by asking important empirical questions both about the efficacy of current antidiscrimination laws and the variables underlying the development of effective antidiscrimination law. Social science has played the weakest role, however, in the area where it may well have been the most helpful – that is, in developing the law's basic concepts of discrimination (Nelson et al., 2008).

In the employment discrimination field, expert testimony from social scientists is a necessity in disparate impact and pattern and practice cases. At a minimum, several types of social scientific expertise must be brought into a case. In both disparate impact and pattern and practice cases, labor market experts are necessary to formulate and to defend definitions of the relevant labor market, using census data, industry surveys, and other sources. Testing psychologists (psychometricians) play a crucial role in disparate impact cases, both in designing employment screening tests in such a way as will allow them to withstand legal scrutiny and in challenging the designs of tests in litigation. Statisticians are needed in both types of cases to ensure that appropriate data are collected through the court-administered evidence discovery process, to formulate an affirmative case from the data, and to critique the rival statistical story being told by the opposing party. Sociologists testify as to the characteristics of workplaces that are likely to generate discriminatory practices ("social framework evidence") (Hart and Secunda, 2009; Fiske and Borgida, 2013.). Expertise from a number of disciplines is drawn upon to demonstrate or to refute the extent to which underrepresentation of groups results from their lack of interest in particular categories of jobs (e.g., Schultz, 1990). Thus, disparate impact and pattern and practice cases are universally viewed as battles of the experts – which is a problem for the untrained judges and juries who must evaluate the evidence. Expert testimony has also found its way into individual disparate treatment cases. In *Price Waterhouse v. Hopkins* (490 US 228 [1989]), for example, expert testimony was admitted in order to demonstrate that certain statements by supervisors were based on sexual stereotypes (see Antczak, 2011).

While employment discrimination litigation employs the talents of psychologists, labor economists, sociologists, and statisticians, the field of voting rights has brought political scientists into the expert witness role. Legislatures employ sophisticated demographic and political models when they redistrict, and the political scientists who create these models have played an important role in defending them and their results in court. Educational desegregation litigators utilize the expertise of specialists not only in education but also in demography, because patterns of housing segregation play an important role in long-term educational segregation.

Outside of the courtroom context, social scientists have questioned the effectiveness of existing antidiscrimination

frameworks both in the United States and elsewhere (e.g., Donohue and Heckman, 1991; McCrudden et al., 1991; Edelman, 1990). Social scientists are engaged in a raging debate on whether race-based affirmative action in higher education helps or hurts its beneficiaries (compare Sander, 2004 with Chambers et al., 2005).

Where social science has played less of a role is in the development of the law's basic concepts of discrimination. Contemporary studies of prejudice in numerous disciplines are critical of the intent-based model of discrimination that permeates American law (Nelson et al., 2008). A large body of work in the field of cognitive psychology has demonstrated that whites' reaction times to pairings of words with images of black faces are far faster when the words are negative than when they are positive. Calling this reaction-time disparity 'implicit bias,' scholars have argued that this form of subconscious discrimination is pervasive (not only for race, but also for gender, national origin, and disability) and that it calls into question the intent-based paradigm in American antidiscrimination law (Kang and Lane, 2010; Krieger and Fiske, 2006). (Project Implicit makes implicit association tests available on line at https://implicit.harvard.edu/implicit/takeatest.html.)

It is too soon to know whether implicit bias research will come to play a role in American antidiscrimination law. Some critics contend that the research method does not adequately model decision-making outside the laboratory. Others argue that the very prevalence of 'implicit bias' means that the phenomenon cannot, in fact, be something the law ought to categorize as a legally prohibited wrong (Mitchell and Tetlock, 2006; for responses, see Jost et al., 2009; Eyer, 2012). Perhaps, for these skeptics, implicit bias research is too pessimistic both about human nature and about the efficacy of existing legal approaches and remedies. Even some supporters of the research question whether "an expert can validly determine whether implicit bias caused a specific employment decision" (Faigman et al., 2008 at 1394). Rather than trying to fit implicit bias into litigation fact-finding, they argue that the phenomenon is best addressed through systematic changes in the structure of the institutions in which discrimination takes place.

International Developments

As other nations and transnational entities address the discrimination in their own midst, they learn not only from their own histories but also from the successes and the failures of the American model. A few examples in which other countries have gone beyond the American model illustrate the possibilities.

In the United States, the disparate impact principle (or, as it is often known outside the United States, the 'indirect discrimination' principle) has been limited to circumstances in which statutes expressly specify its use. However, that principle has been embraced in numerous national and international framework laws (treaty or constitutional), including the International Convention on the Elimination of All Forms of Racial Discrimination, the European Union's Racial Equality Directive, and the Constitution of South Africa (Daniel, 2011). The law of free speech under the First Amendment of the United States Constitution has stood in the way of pervasive hate speech regulation in the United States. In contrast, out of the historical experience of Germany has grown a strong commitment in German and European law to prohibiting the group-hate speech exemplified by expressions of anti-Semitism (Kahn, 2013; Schauer and Pildes, 1999; Stein, 1986; Waldron, 2010).

In the field of gender discrimination in employment, the theory of 'comparable worth' is an important part of the gender discrimination law of the European Community and some of its member states (e.g., Linos, 2010; Ellis, 1998; Libeson, 1995). In comparable worth analysis, women use the tools of job and wage analysis to demonstrate that they do not receive the same returns on effort, education, and skill as do occupants of traditionally male jobs. Despite its importance in European jurisprudence, comparable worth has not made significant inroads into American law (Blum, 1991).

In the field of affirmative action (under its many names), Indian law has 'reserved' scarce positions, including legislative seats, for members of 'backward castes and classes' for decades (Galanter, 1984). In South Africa, the postapartheid constitution explicitly permits affirmative action (Adam, 1997; Higginbotham, 1999), and employs concepts of positive social and economic rights that the United States has never embraced (Sachs, 2000).

Abstract

In the abstract, 'discrimination' refers to distinctions or differentiation made among objects or individuals. In economics, as in ordinary parlance, discrimination typically carries a pejorative connotation. The term is generally reserved for distinctions that are socially unacceptable and economically inefficient. Economic theories of discrimination can be categorized into theories about tastes and preferences of economic agents, economic power, and statistical discrimination. Achieving a consensus on what the broad features of discrimination in markets, especially labor markets, should entail is a seemingly straightforward task compared with obtaining a consensus on empirical measures of discrimination. The standard measurement technique is that of wage decompositions. With the advent of newer and more sophisticated econometric methods for estimating earning relationships, measurement of discrimination has become more ambiguous. Legal and employee morale considerations constrain attempts to remove discrimination in the workplace in a way that would correspond to accepted economic principles of efficiency. Comparable worth seeks to remedy discrimination by relying upon experts to value job attributes in an unbiased manner. Empirical studies of labor-market discrimination are global in nature and encompass both developed countries and developing countries.

Discrimination

In the abstract, 'discrimination' refers to distinctions or differentiation made among objects or individuals. In economics, as in ordinary parlance, discrimination carries a pejorative connotation. The term is generally reserved for distinctions that are socially unacceptable and economically inefficient. Economic theories of discrimination usually fall into one of three broad categories: tastes and preferences of economic agents, economic power, and statistical discrimination. Unlike the world of theory, empirical documentation of discrimination is subject to much ambiguity and differences of interpretation.

Theories of Discrimination

Tastes and Preferences

Publication of *The Economics of Discrimination* (1957) by Gary Becker was instrumental in making discrimination a legitimate and popular topic for study by economists. The tastes and preferences approach adopted by Becker was pure neoclassical economics. This approach appeals to tastes for discrimination by utility-maximizing economic agents. Tastes for discrimination are embodied in discrimination coefficients that are susceptible to measurement by the economist's monetary yardstick. Agents' tastes for discrimination are manifested by a desire to minimize economic transactions with members of certain demographic groups. While discriminating agents may be prepared to forfeit income in order to indulge their tastes, the effects of their discriminatory behavior can lead to segregation or reduced incomes for the groups discriminated against. In addition to employer tastes for discrimination, Becker also considered the effects of tastes for discrimination by consumers and fellow workers. Under some circumstances, competitive pressures can ameliorate the effects of discriminatory behavior.

The literature provides support for Becker's contention that labor-market discrimination is lessened by product market competition. Ashenfelter and Hannan (1986) present statistical evidence that within the banking sector the employment opportunities for women are negatively related to market concentration. Peoples and Saunders (1993) show that deregulation of trucking in the USA lowered the white/black wage ratios among both union and nonunion drivers. This competitive effect was identified with the reduction of rents accruing to whites.

One avenue for exploring the effects of discrimination by fellow workers is to examine the effects of unionism on racial wage differentials. An early study by Ashenfelter (1972) showed that the average wage of black workers relative to the average wage of white workers in the USA was higher in the union sector than in the nonunion sector. In particular, Ashenfelter estimated that compared with the complete absence of unionism, the black/white wage ratio was 4.0% higher in the industrial union sector, and 5.0% lower in the craft union sector. These results suggest that the union sector is less discriminatory than the nonunion sector, and that industrial unions are relatively more egalitarian compared with craft unions. Peoples (1994) found evidence not only that the returns to union membership are higher for blacks than for whites, but also that racial wage differentials were higher among nonunion workers in the highly concentrated industries.

Market Power

Prior to Becker, early work by economists on the topic of discrimination focused on pay differentials between men and women. Joan Robinson's (1933) classic on imperfect competition provided an early example of the economic power theory of discrimination. Robinson considered the case of a monopsonistic employer (single employer labor market) of men and women who are equally productive (perfect substitutes in

production). She proved that if the labor supply elasticity (responsiveness to wages) were smaller for women, a profit-maximizing employer would equate the incremental employment costs of men and women by offering women a lower wage.

Madden (1975) explored the circumstances under which the labor supply elasticities of women would be lower, and how male monopoly power insulates men from any monopsony power that might exist in labor markets. The key element was the existence of job segregation, which reduced competition from women. It was shown that under these circumstances women would receive lower wages than men, if both worked in equally productive, but different, sets of jobs. Earlier, Bergmann (1971) advanced the occupational crowding hypothesis to explain income inequality between white male workers and otherwise equally capable nonwhite workers. Crowding nonwhites and women into a narrower range of occupations raises the incremental value of white males in their occupations and lowers the incremental value of all workers in the occupations dominated by nonwhites and women.

The ubiquity and self-reinforcement of a broad range of discriminatory behavior in society was examined in Thurow (1969). For example, discrimination in schooling opportunities has the effect of diminishing the subsequent earnings potential of minority workers. This reduces the costs to discriminating employers of paying lower wages to minority workers, as the latter will have fewer skills to begin with. Lower wages reduce the cost of housing discrimination because better housing is beyond the incomes of most minority workers.

Statistical Discrimination

Statistical discrimination is an approach that relies upon risk and information costs rather than tastes for discrimination or market power to explain income disparities among different demographic groups in society (Aigner and Cain, 1977). One example is that of two groups who are equally productive on average, but the productivity signal, for example, test scores, is a noisier signal of productivity for one of the groups. A risk-averse, profit-maximizing employer might offer lower wages or less desirable positions to applicants from the demographic group with the noisier signal. Consequently, employment decisions are made on the basis of group characteristics and individual characteristics.

Wage Decompositions

In the study of wage inequality, the most commonly used methodology for apportioning wage gaps between two demographic groups to productivity and discrimination can be traced to Blinder (1973) and Oaxaca (1973). The basic idea is quite simple. One first estimates wage equations for each of the demographic groups from a sample of workers. These wage equations are mathematical formulas relating wages to observed productivity factors such as education and experience. In the absence of direct labor-market discrimination, equity is characterized as a situation in which both demographic groups are expected to be compensated according to the same wage (salary)-determination formula. In this scenario the only reason for the existence of a wage gap would be that the two groups differ on average with respect to the observed wage (productivity)-determining characteristics. This wage gap is commonly referred to as the 'endowment' or human capital effect.

The difference between the actual wage gap and the endowment effect is often referred to as the 'unexplained gap.' Many practitioners regard the unexplained gap as an estimate of discrimination. Those who prefer the term 'unexplained gap' reason that this estimate is in the nature of a residual and as such may include the effects of productivity factors not explicitly taken into account in the wage-determination formula. Hence, the measure may be a biased estimate of discrimination. From an econometric standpoint, the bias can go in either direction. The counterargument is that there are always factors omitted from any statistical relationship and that there is no reason to suppose that these are anything but random in the present context. In addition, the same sort of methodology is very commonly used to estimate other types of wage gaps, for example, union/nonunion, north/south, manufacturing/nonmanufacturing. In these contexts the term 'unexplained gap' is not used.

According to the Blinder/Oaxaca standard decomposition methodology, one of the two demographic comparison groups is designated as the reference group. If, for example, one is interested in male/female wage differentials, one might select males as the reference group. This means that the statistically estimated wage formula for males serves as the nondiscriminatory wage structure. Operationally, one estimates the average wages for both males and females by applying the estimated male wage formulation to each group's wage-determining characteristics. The gender difference in these predicted average wages is the 'endowment' effect, since the same wage formula is applied to the characteristics of both groups. The difference between the original unadjusted wage gap and the gap attributable to the 'endowment' effect is by definition the result of different wage formulas for males and females. This residual gap is what is termed either the 'unexplained gap' or the gap attributable to direct labor-market discrimination. Therefore, the decomposition technique is a method for decomposing an observed wage gap into an endowment component and an unexplained/discriminatory component.

Identification of Individual Components of Discrimination

Apart from differences in what researchers call the 'residual gap,' there are other ambiguities in the standard decomposition technique. First, it would seem desirable to be able to identify the contribution of each wage-determination characteristic to the endowment component and the discrimination component. For example, one could identify the contribution of gender differences in a characteristic such as work experience to the overall endowment effect as the gender difference in average work experience multiplied by the pecuniary return to an additional unit of work experience estimated from the male wage equation. Or consider the case of a wage-determining characteristic defined by a set of mutually exclusive categories such as educational levels, for example, 'less than high school,' 'high school,' 'some college,' and 'college graduate.' The estimated return to each included educational category is relative

to the return on an arbitrarily selected educational category variable that is omitted from the wage equation. The monetary value of gender differences in the proportion of workers in the sample who are college graduates is simply calculated as the gender difference in the proportion of college graduates weighted by the estimated value of a college education for males relative to the omitted educational category. The sum of all of these endowment valuations equals the overall endowment effect.

Unfortunately, an identification problem can arise when one attempts to estimate the contribution of each wage-determination characteristic to the discrimination component. The problem is initially described in Jones (1983) and further extended in Oaxaca and Ransom (1999). For example, weighting the average amount of work experience for females by the male–female difference in the estimated return to an additional unit of work experience would constitute a measure of the contribution of gender differences in the return to experience to the overall discrimination measure. It turns out that this computation is affected by a simple shift in the experience measure. For example, potential experience is commonly calculated as either schooling-age-five or schooling-age-six. This is a seemingly innocuous shift in the experience measure, yet it will affect the estimated contribution to discrimination of gender differences in the return to experience. Because this change in the experience measure creates an offsetting change in the intercept term in the wage equations for males and females, it does not affect the overall estimate of discrimination. Nor does this change in the experience measure have any effect on the contribution of gender differences in work experience to the endowment effect.

This arbitrariness is more manifest when attempting to estimate the contribution to discrimination of gender differences in the returns to a variable defined by mutually exclusive categories. Returning to the education example, note that the contribution to measured discrimination of the gender difference in the returns to education is calculated as the sum of the gender differences in the estimated returns for each included educational category weighted by the proportion of females who are in each included category. As it turns out, this calculation is affected by the choice of which educational category variable is to play the role of the omitted reference category. The choice of omitted reference category is of course quite arbitrary. Fortunately, the overall estimated discrimination component is not affected by which categorical variables are selected to be the omitted reference categories. Also, the choice of omitted reference group has no effect on the estimated contribution to the endowment effect of gender differences in the values of the categorical variables.

Nondiscriminatory Wage Structures

To examine a second source of ambiguity in standard wage decompositions, imagine that the choice of reference group is reversed so that female workers are designated as the reference group. Now one estimates the (nondiscriminatory) average wages for both males and females by applying the estimated female wage formulation to each group's wage-determining characteristics. An ambiguity arises in that in general estimates of the endowment and discriminatory wage effects will depend on which demographic group is serving as the reference group. This ambiguity is a manifestation of the familiar index number problem. The researcher is trying to measure 'value' using alternative base weights.

As a measure of discrimination, the estimated residual gap is subject to quite different interpretations depending on the choice of reference group. The situation is one in which the presence of discrimination is manifested as a wage gap based on the fact that in actuality men and women do not face the same wage-determination process. This can be viewed as either that women are underpaid relative to the male wage structure or else that men are overpaid relative to the female wage structure. The interpretation and estimated magnitude of each of the two components comprising the original unadjusted wage gap depend on which group's wage structure is regarded as the nondiscriminatory standard. To further add to the ambiguity surrounding wage decomposition analysis, there is the theoretical possibility that which group is being discriminated against depends on whose wage-determination formula is being used as the nondiscriminatory standard.

It is clear that the second type of ambiguity surrounding the standard wage decomposition analysis has to do with identifying an appropriate nondiscriminatory wage standard. Ideally, one would want the wage structure that would prevail in a nondiscriminatory world to serve as the standard by which to measure actual discrimination. Under some assumptions, such a wage structure would be the one that would exist in a world characterized by perfect competition in product markets and labor markets. One would estimate the average wages for both males and females by applying the nondiscriminatory wage formulation to each group's wage-determining characteristics. The gender difference in these predicted average wages is the endowment effect. Again, discrimination is measured by the unadjusted gender wage gap net of the endowment effect. However, it is now possible to further decompose the discriminatory wage gap because the gap is, in general, the sum of two distinct components. The first component is the difference between the actual average wage of the male workers, and their predicted average wage based on the nondiscriminatory structure. The second component is the difference between the predicted average wage of females based on the nondiscriminatory wage structure, and their actual average wage.

These discriminatory wage components have interesting interpretations (Neumark, 1988). The first component is a measure of the male wage advantage relative to the nondiscriminatory norm. This component can be viewed as favoritism toward males. The second component is a measure of the female wage disadvantage relative to the nondiscriminatory norm. This component can be viewed as pure discrimination against female workers. This methodology, in principle, allows researchers to sort out how much of the male–female discriminatory wage gap results from overcompensation of men, and how much stems from undercompensation of women. In the light of this approach, the conventional decomposition method is seen as a special case.

While seemingly attractive as a decomposition method, there is a practical difficulty in making operational the concept of a nondiscriminatory wage structure. One notion is the wage structure that would prevail had discrimination never existed. A slightly less challenging task might be to define the

nondiscriminatory wage structure as the structure that would emerge in the immediate aftermath of a cessation of discrimination. In general, this is not the same as the wage structure that would have prevailed had discrimination never existed. This is because of a likely path-dependence feature in which discrimination permanently alters the evolution of wage structures. While a still formidable enterprise, it is possible to reach useful approximations to a wage structure that would emerge after the cessation of discrimination.

The basic idea underlying this approach is contained in Neumark (1988) and Oaxaca and Ransom (1999). A reasonable presumption is that with the cessation of discrimination between two demographic groups, the resulting wage structure would, in some way, be related to the preexisting separate wage structures. A natural approximation is the wage structure that is estimated on the basis of a combined sample obtained by pooling the data on the two demographic groups. Such a common wage structure can be shown to be a matrix-weighted average of the separately estimated wage structures. The weights are related to the precision by which each group's wage-equation parameters are statistically estimated. Neumark (1988) applies this methodology to the gender wage gap.

In Oaxaca and Ransom (1994), the methodology is generalized to allow for estimation of a nondiscriminatory wage structure as any matrix-weighted average of the separately estimated wage structures. Without restrictions on the weighting matrices, any common wage structure can be rationalized as a matrix-weighted average of the separately estimated wage structures. Reimers (1983) uses simple averages of separately estimated wage structures when comparing whites, blacks, and Hispanics.

Residual Decomposition

An important aspect of the study of wage inequality is trying to understand the components of changes or trends in wage inequality. Juhn et al. (1991) introduce a method of decomposing changes in the residual wage gap between two demographic groups into the effects of changes in the average rankings of the two groups in the residual wage distribution of the dominant group, and the effects of changes in the residual wage dispersion (standard deviation) of the dominant group. This approach is referred to as the Juhn–Murphy–Pierce (JMP) decomposition. It follows the practice of interpreting the wage gap left after controlling for group differences in observed characteristics as an unexplained differential.

In Blau and Kahn (1996), the JMP decomposition is adapted to analyzing gender wage gap differences between nine countries and the USA during the 1980s. Earnings are standardized to a full-time (40 h) work schedule. The earnings models estimated with microdata sets control for education, potential experience, union membership, industry, and occupation. **Table 1** summarizes the Blau and Kahn findings in which the gender wage gaps in each country are compared with that of the USA. Column 2 reports the raw (log) wage differentials by country. The wage gaps range from 0.258 log points (approximately 26%) in Sweden to 0.4875 log points (approximately 49%) in the UK. Column 3 reports each country's wage gap minus that of the USA. It is this difference that is decomposed into the effects of international differences in the following: (1) gender differences in human capital characteristics (quantities), (2) the (male) returns to human capital characteristics (prices), (3) gender differences in the percentile rankings in the male wage residual distribution (rankings), and (4) differences in the (male) standard deviation of the wage residuals (dispersion). In six of the nine countries, the male human capital advantage is greater than that of the USA. Without exception, international differences in the returns to human capital and in the dispersion of wage residuals lower the gender wage gap in other countries relative to the USA. In six of the nine countries the less favorable rankings of women in the male wage residual distribution widens the gender wage gap relative to the USA. What emerges from this study is that the gender wage gap is relatively high in the USA because the greater wage residual inequality in the USA more than offsets the greater relative human capital of the US women.

Correcting Wage Inequities

Although economists are presumably interested in measuring the extent to which discriminatory wage gaps represent overpayment of the dominant group versus underpayment of the

subordinate group, custom and the legal environment lean more to the dominant group's wage structure as the nondiscriminatory standard. The idea is that inequities should be addressed by raising the wages of the subordinate group, as opposed to lowering the wages of the dominant group. Indeed, the US Civil Rights Act of 1964 prohibits equity wage adjustments that involve lowering any group's nominal wages. Thus, attempts to remove discrimination in the workplace in a way that would correspond to accepted economic principles of efficiency are constrained by legal and employee morale considerations.

Econometric Modeling Approaches

One might properly speculate about how econometric models of the wage-determination process can be used to address a salary inequity issue in the workplace. Examples from legal practice are provided in Finkelstein (1980). Oaxaca and Ransom (1999) report on several approaches on how to use statistical salary models to correct salary inequity within a firm. For illustrative purposes, the examples are in terms of gender inequity, but the methodology extends without modification to racial or ethnic salary inequity. The remedies range from simply compensating each female worker exactly according to the estimated male wage equation to constraining the salary equity adjustment process to award minimum settlements regardless of personal circumstances.

Comparable Worth

Comparable worth is a general policy for eradicating discriminatory wage disparities within firms. The idea behind comparable worth is that jobs of equal value should pay equal wages. While this sounds like free market economics, at issue is how value is determined (Hill and Killingsworth, 1989). Advocates of comparable worth envision a system in which points are awarded to each job based on the skills, effort, and responsibility required. Experts are responsible for evaluating a firm's jobs in a manner that does not bias wage determination against women. The objection against letting the market value the jobs is that occupational segregation dooms women to a subordinate wage position. An important question is whether or not comparable worth would provide employers with the incentives to eliminate job segregation, and whether or not women would switch among occupations that were equally compensated. Critics of comparable worth fear the massive inefficiencies that could emerge from interference with labor-market resource allocation.

Self-Selection in the Labor Force

Estimation of labor-market discrimination, in general, is complicated by the observation that individual workers in a statistical sample generally do not constitute a random sample of the adult population. Whether or not to participate in the labor force will depend upon the individual's calculation of the net benefits of labor force participation. While the net benefits are unobserved by researchers, the decision to participate is observed, as well as many determinants of the net benefits. For women, the presence of small children at home would likely be a factor in the decision to be in the labor market. The statistical equation corresponding to labor force participation is known as a selection equation, since it describes a rule for individuals to select themselves in or out of the labor force.

Sample selection bias can arise when the random statistical errors in the selection equation are correlated with the random statistical errors in the wage equation that is being estimated for a self-selected sample of workers (Heckman, 1979). Unless the probability of selection (which depends on the selection equation) is taken into account, the estimated parameters of the wage equation can be biased. The selection probabilities for the selected sample are controlled for in a variable known as the inverse Mills ratio. This variable is constructed from the variables and parameters of the selection equation.

A number of studies have attempted to correct for sample selection bias when dealing with occupational segregation or more generally labor-market discrimination (Reimers, 1983; Dolton et al., 1989; Neuman and Oaxaca, 1998). Neuman and Oaxaca (1998) explore alternative ways of estimating (ethnic and gender) labor-market discrimination from selectivity-corrected wage equations using a sample of Jewish professional workers drawn from the Israeli 1983 Census of Population and Housing.

Progress and Future Directions

Smith and Welch (1989) chronicle the economic progress of African-Americans over a 40-year period. Black male wages as a percent of the white male wage rose from 43.3% in 1940 to 72.6% by 1980. The documented wage gains of African-Americans were largely attributed to more and better education, migration, and general economic growth. Some evidence was found that affirmative action policies improved the employment and wage prospects of African-Americans. Data from the US Current Population Survey are consistent with the Smith and Welch findings. The median income of full-time, year-round black workers as a percent of the median income of full-time, year-round white workers rose from 68.1% in 1970 to 73.9% in 1998.

Empirical findings from gender labor-market studies are quite mixed, variable over time and across countries. Zabalza and Tzannatos (1985) examine the gender employment and wage effects of labor-market legislation in the UK on the employment and wages of women. Panel data, which contain detailed information on individuals over their working lives, have been used to study gender wage gaps in Denmark (Rosholm and Smith, 1996). In a shift of emphasis from gender wage discrimination Flückiger and Silber (1999) examine both theoretically and empirically the phenomenon of gender labor market segregation with special emphasis on the Swiss labor market.

Empirical studies of racial-, ethnic-, gender-, and caste-based labor-market outcomes in developing countries may also be found (Birdsall and Sabot, 1991; Psacharopolulos and Patrinos, 1994). Intercountry comparisons of labor-market inequity between the developed and the developing countries will be the inevitable result of globalization. The implications

of labor-market discrimination for international trade and specialization should occupy the attention of social scientists well into the twenty-first century.

Discrimination: Racial

Abstract

Racial discrimination exists in straightforward actions but also in complex systems of social relations that produce racial inequities in social outcomes. Some analysts view all racial disparities as the result of discrimination; others restrict the concept to those acts intended to limit a group's resources. The first view is too broad, the second too restrictive.

Social scientists have made a useful distinction between direct and indirect discrimination. The direct form occurs at points where inequality is generated, usually intentionally. The indirect form develops when the inequitable results of direct discrimination influence later decisions; it perpetuates and magnifies the original injury. After a brief review of racial discrimination and its effects and remedies in North America and Western Europe, two summary propositions are advanced. First, discrimination is normative. Its structural web outlives its initiators and may not reflect current attitudes. Second, discrimination feeds upon itself; it is typically cumulative and self-perpetuating. Effective remedies must intervene and reverse its 'vicious circle.'

Racial discrimination is not, as popularly thought, simply the accumulation of individual acts of unfairness between members of different groups. It consists as well of an elaborate web of institutional arrangements that produces group inequalities, a web that becomes racial discrimination when the groups perceive each other as separate 'races.' Studied throughout the social sciences, these inequalities can involve political power, economic resources, and cultural access.

Conceptual Complexities

Viewing racial discrimination as an institutional web casts a wide net but leaves room for considerable ambiguity. Disagreement about what constitutes discrimination stems from two sources – one ideological and political, the other empirical. First, because discrimination violates law and professed values in many countries, a judgment that unequal outcomes reflect discrimination is a call for unpopular change and costly remedies. Resistance to such change and costs activates debate about the extent of discrimination. Second, deficiencies in analysis and evidence limit the ability of social scientists to trace precisely the dynamic system of effects triggered by discrimination.

Consider first the political issue. The broadest definitions of discrimination assume that racial minorities have no inherent characteristics that warrant inferior social outcomes. Thus, all inequality becomes a legacy of discrimination and a social injustice to be remedied. Favored by the political left, this view appears to many to be too sweeping.

By contrast, political conservatives favor a narrow definition that limits the concept's scope by including only actions intended to restrict a group's chances. Most social-science specialists resist this reformulation for several reasons. An intentionality criterion returns the concept to the realm of psychology and deflects attention from restraining social structure. And the invisibility of intentions creates formidable obstacles for substantiating discrimination. Finally, the effects of discrimination are the same, whether or not the causal institutional mechanisms were intended to produce group inequalities.

This rejection of the intentionality criterion leads to an important distinction between direct and indirect discrimination (Pettigrew, 1985). Direct racial discrimination occurs at points where inequality is generated, often intentionally. When decisions are based explicitly on race, discrimination is direct. Indirect discrimination occurs when the inequitable results of direct discrimination serve as a basis for later decisions. Hence, discrimination is indirect when an ostensibly nonracial criterion becomes a proxy for race in determining social outcomes. Indirect discrimination perpetuates and magnifies the original injury.

Wage discrimination illustrates the distinction. Direct racial discrimination exists when employers pay equally qualified members of two races different rates for the same work. Indirect discrimination exists when the employers pay the two groups unequally because prior discrimination in employment, education, or housing created apparent differences in qualifications or channeled the groups into better- and worse-paying jobs. This direct/indirect distinction resembles the distinction often made by legal systems between disparate treatment and disparate impact. Although intentional, direct discrimination may have triggered the causal chain, the original injury is perpetuated and magnified by largely unwitting accomplices. To be sure, these accomplices typically benefit from the discriminatory arrangements and have little incentive to alter them. But the important point is that these beneficiaries of the discriminatory practices did not initiate them and may not even be aware of their operation.

The direct/indirect distinction is reflected in the psychological differentiation between conscious and unconscious discrimination. Those who are conscious of their abetting racial discrimination are typically racially prejudiced. They explicitly intend to harm and regard it as justified. But most people who engage in racial discrimination are largely unaware that they are doing so. They are simply following their in-group norms and participating in the subtle forms of indirect discrimination. Social psychologists view this as in-group favorability without

 http://dx.doi.org/10.1016/B978-0-08-097086-8.32044-X

explicit intent to harm the out-group. Thus, the link between racial prejudice and racial discrimination is not nearly as firm as is commonly believed.

Empirical Ambiguities

This conceptual and psychological complexity carries over to impede the empirical study of discrimination. Apparently rigorous quantitative analyses often camouflage the crucial issues, as an examination of wage decomposition research reveals.

Assessments of racial discrimination produced by decomposing gross racial differences in social outcomes are common in sociology and economics. This approach first assigns one segment of the gross racial differential to 'qualifications' and other factors deemed legitimate determinants of social rewards. The residual segment not demonstrably linked to these 'legitimate' determinants of the outcomes often is presented as the estimate of discrimination. However, without better information than is usually available and without closer agreement about what constitutes discrimination, no unique estimate of discrimination is possible. The choice of control variables to index 'legitimate' determinants of social outcomes shapes the answers. Any appearance of scientific certitude is an illusion. It is not surprising that discrimination estimates originating from this approach vary enormously.

Empirical research in group discrimination must mirror the phenomenon in its variety and complexity. The regression decomposition approach is useful but limited. Regression analyses could provide more pertinent information if based on more homogeneous job groups (Conway and Roberts, 1994) and on structural equation models that test reciprocal causation. Most important, if the aim is to guide policy, a framework far more complex than the dichotomous discrimination-or-not approach is required. Research that traces the actual processes of institutional discrimination is essential. Also needed is more attention to victims' perceptions of discrimination and to the changes generated by antidiscrimination efforts.

Racial Discrimination in the United States and Western Europe

Both direct and indirect forms of racial discrimination can be found throughout the world. Most of the available research, however, focuses on the long-festering racial problems of the United States (Pager and Shepherd, 2008). In such long-term situations, injuries of indirect discrimination often are more extensive than those of direct discrimination. This conclusion does not imply that direct discrimination no longer exists. Employment complaint records reveal the continued operation of direct forms of discrimination. US women and minorities have filed almost two million job-discrimination complaints since 1965. Not all such complaints reflect genuine discrimination, but analysts believe that false complaints are minimal in comparison with the amount of actual discrimination that goes unreported and thus undetected (Tomaskovic-Devey and Stainback, 2007). Many major corporations have been found guilty of direct racial discrimination in recent years. And employment audits using paired, equally qualified applicants reveal widespread direct discrimination. Employers admit to interviewers that their stereotypes of minorities, particularly of inner-city black men, lead them to avoid minority hiring (Reskin, 1998).

Along with direct employment discrimination, indirect discrimination is pervasive. Many employers rely on word-of-mouth recruiting of new employees, especially for unskilled jobs. Thus the current workforce, often disproportionately white, reproduces existing racial inequalities in employment by bringing in white friends and relatives as the next generation of workers. This is just one aspect of 'business-as-usual' that represents indirect discrimination. Although word-of-mouth recruiting appears to be color blind, it serves to perpetuate racial inequalities (Reskin, 1998).

Note, too, how this structural process of indirect discrimination can operate without explicit racial prejudice being involved. Racial discrimination is often viewed as a psychological rather then a structural, phenomenon. Prejudiced members of the dominant race are thought to cause the racial unfairness intentionally. But white American workers nominating white friends for job openings simply reflects the society's widespread racial segregation; African Americans are not in their friendship networks. White nominators need not have hostile views of blacks to engage in this virulent form of indirect discrimination.

Important analyses of indirect discrimination in the United States focus on wealth. Racial inequalities in assets dwarf disparities in other social outcomes. Although the magnitude of inequality in home equity in severe, racial inequality in liquid assets is even more marked. The average white American family was estimated in 2007 to hold liquid assets 20 times greater than those of the average African American family – roughly $100 000 compared with only $5000. Moreover, this racial gap in assets has been accelerating since the 1980s (Shapiro et al., 2010).

This racial difference in assets results from a history of direct and indirect discrimination. Prohibitions against black self-employment and land ownership in the American South were an early part of the picture. More recently, occupations to which African Americans were confined, agricultural and domestic work, were excluded from Social Security provisions. Direct and indirect discrimination by federal housing agencies, banks, realtors, and white homeowners have limited the opportunity of African Americans to accrue wealth through home ownership (Conley, 1999; Rank, 2009; Shapiro, 2004).

The sharp economic recession that began in 2008 and centered on housing made matters worse. African and Hispanic Americans were among the hardest hit in home foreclosures and other asset-reducing events.

The accumulation of disadvantage is particularly acute when the focus is assets. Because wealth reproduces itself exponentially, the racial gap in assets in the United States has continued to grow. And assets have important implications for such other social outcomes as education and labor market success. When parents do not have the means to live in higher status neighborhoods, children do not have access to the best public schools. And for most students, attendance at the best colleges and universities increasingly depends on

parents' ability to provide thousands of dollars per year to cover rising tuition costs and expenses. Labor market outcomes reflect educational disadvantage, but restricted assets have other indirect effects as well. Access to networks of information crucial to job seekers, proximity to lucrative employment, automobile transportation to work – all these are functions of assets, and African Americans are at a pronounced disadvantage (Conley, 1999). Innovative strategies for intervention must be devised to break into the spiraling disadvantage produced by African Americans' deficits in wealth.

Analogous dynamics afflict the minorities of other nations, and research literature concerning the subject has emerged in Western Europe. Discrimination against the region's new immigrant racial minorities is pervasive (Pettigrew, 1998). A third of all minority respondents in a Europe-wide survey reported they had been personally discriminated against, and 12% felt they had been a victim of a racially motivated crime in the past 12 months (European Union Fundamental Rights Agency, 2010). The Roma and black Africans are particular targets. Survey results in France show an even sharper degree of perceived discrimination; 61% of minority respondents believed, in 2007, that they had experienced discrimination in the past year (BBC News, 2007).

Both direct and indirect discrimination are involved, though the indirect forms are largely unrecognized in Europe. Investigators have repeatedly uncovered direct discrimination. Controlled tests have revealed the full litany of discriminatory forms involving employment, public accommodations, housing, the courts, police, insurance, and banks. Police stops and searches in the United Kingdom, for example, indicated that per 1000 population in 2009 and 2010, blacks were seven times more likely to be stopped and searched by police than were whites (UK Justice, 2012).

Employment discrimination poses the most serious problem. In every European Union nation, minorities have markedly higher unemployment rates than native majorities. As in the United States, there are many reasons for disparities in minority unemployment. The 'last-in, first-out' principle selectively affects the younger minority workers. Typically less skilled, they are more affected by job upgrading. Minorities also are more likely to be in older, declining industries. These patterns are not accidental. Planners put minorities into these industries for cheaper labor precisely because of their decline. Yet these multiple factors offer insufficient explanations for the greater unemployment of minorities. Veenman and Roelandt (1990) found that education, age, sex, region, and employment level explained only a small portion of the differential unemployment rates in the Netherlands.

Indirect discrimination arises from the inability to obtain citizenship. It restricts immigrants' ability to get suitable housing, employment, and schooling. In short, the lives of Europe's noncitizens are severely circumscribed. Castles (1984) contends that the guest-worker system that brought many of the immigrants to Europe was itself a state-controlled system of institutional discrimination. It established the newcomers as a stigmatized out-group suitable for low-status jobs but not citizenship, and racial prejudices add to this stigma. Widespread indirect discrimination, then, was inevitable for these victims of direct discrimination.

Psychological Effects of Racial Discrimination

Social psychologists have examined extensively the effects of discrimination on its victims. Multiple studies show that when people perceive themselves to be the targets of systematic discrimination, their physical and psychological health often suffers. Moreover, perceived discrimination both increases the likelihood of engaging in dangerous and unhealthful behaviors and decreases the likelihood of performing healthful behaviors (Pacoe and Richman, 2009). These effects are mediated largely by increased stress, and they have been found in a variety of ethnic groups, including whites. Greater drug use among those perceiving discrimination is part of this process (Gibbons et al., 2004).

Discrimination also heightens victims' awareness of any cultural stigmatization of their group. Such 'stereotype threat' can be stressful and hinder performance. It is triggered by situations that contain cues that make a negative stereotype salient. This situation raises the strong possibility that one's own performance will conform to the stereotype and confirm it. Such a threat creates anxiety and undermines performance. Thus, African Americans tend to score higher on intelligence tests when they take the test apart from white Americans. Stereotype threat is not unique to racial minorities; women tend to score higher on tests of mathematics when there are no men in the situation (Steele, 2010).

Remedies for Racial Discrimination

The most elaborate array of remedial measures for racial discrimination is found in North America. Both Canada and the United States have instituted a battery of laws against many types of racial and other forms of discrimination. Court rulings in the two nations also have proven decisive. The effects of these legal actions are magnified by class action suits – the ability of single litigants to sue for remedy for their entire 'class' or group. Further remedies have involved various forms of 'affirmative action' in which special efforts are made to close group disparities caused by discrimination. These approaches have led to narrowing racial disparities in social outcomes. But sharp racial inequities remain in both countries, and majority resistance has hardened against the most successful remedies.

Antidiscrimination remedies have been largely ineffective in Europe. Germany guarantees basic rights only to citizens, so the disadvantages of noncitizenship include the inability to combat discrimination. There is extensive German legislation to combat anti-Semitism and Nazi ideology, but these laws have proven ineffective in protecting noncitizens. The German constitution explicitly forbids discrimination on the basis of origin, race, language, beliefs, or religion – but not citizenship. Indeed, the Federal Constitutional Court has ruled that differential treatment based on citizenship is constitutional if there is a reasonable basis for it and if it is not wholly arbitrary. In 2006, Germany, under pressure from the European Union, passed the General Equal Treatment Act (Allgemeines Gleichbehandlungsgesetz – 'AGG'). It prohibits discrimination in the labor market in the access to public services, such as social welfare benefits and housing markets, based on race,

ethnic origin, religion or beliefs, sex, disability, age, or sexual orientation.

Although the AGG does not place the burden of proof on plaintiffs, they must submit the initial evidence to support their claim that discrimination has occurred; then the accused party must prove otherwise. Yet it remains difficult for the plaintiffs to claim their rights. Usually, the victims of discrimination do not know their full rights, and consultancy services are rarely available. It is not surprising that few cases have been brought under the law and fewer still have been successful.

Effective means of combating discrimination are also rare in France. Commentators often view discrimination as 'natural' and as being universally triggered when a 'threshold of tolerance' (*seuil de tolerance*) is surpassed. Without supporting evidence, this rationalization supports quotas and dispersal policies that restrict minority access to suitable housing.

The Netherlands, the United Kingdom, and Sweden have enacted antidiscrimination legislation that applies specifically to the new immigrant minorities. And the Dutch have instituted modest affirmative action programs for women and minorities. Yet this legislation has been largely ineffective for two interrelated reasons. First, European legal systems do not allow class action suits – a forceful North American weapon to combat discrimination. Second, European efforts rely heavily on individual complaints rather than on systemic remedies. The UK's 1976 Act gave the Commission for Racial Equality power to cast a broader net, but individual complaints remain the chief tool (MacEwen, 1995).

Individual efforts are unlikely to alter discrimination because they are nonstrategic. Minorities bring few charges against the worst discriminatory firms because they avoid applying to them. Complaints about job promotion are common, but they are made against employers who hire minorities. Effective antidiscrimination laws must provide broad powers to an enforcement agency to initiate strategic, institution-wide actions that uproot the structural foundations of discrimination.

Two Summary Propositions

1. The long-lasting character of racial discrimination means that the effects typically outlive the initiators of discriminatory practices. Discrimination is fundamentally normative; its structural web operates in large part independent of the dominant group's current attitudes or awareness. Hence, models based primarily on individual prejudice or 'rationality,' whether psychological or economic, will uniformly understate and oversimplify the phenomenon.
2. Discrimination feeds upon itself; it is typically cumulative and self-perpetuating. An array of research on African Americans has shown that neighborhood racial segregation leads to educational disadvantages, then to occupational disadvantages, and thus to income deficits (Pettigrew, 1985). To be effective, structural remedies must reverse this vicious circle of discrimination.

Seen in this perspective, discrimination is far more intricate and entrenched than is commonly thought. The complexity of discrimination presents major challenges to social-scientific attempts to trace its impact. This complexity also precludes any simple correspondence between perpetration and responsibility for remedy. Broad social programs will be necessary if the full legacy of direct and indirect racial discriminations is finally to be erased.

Abstract

Disgust appears to be a universal and basic emotion, perhaps unique to humans. It has become a center of interest in recent research, including psychological, philosophical, evolutionary, and neural perspectives. On the output side, it is characterized by a withdrawal response, a physiological concomitant of nausea, and a distinct facial expression, focused around the nose and mouth. This output system seems to have been relatively constant across time and cultures. However, there has been a major elaboration of elicitors and meanings in cultural evolution, perhaps by a process of preadaptation. Disgust may have originated as a food rejection response in animals, based on taste or smell. However, in humans, the food rejection response is transformed into a rejection based upon the nature or origin of a food, rather than its sensory properties. Disgusting potential foods have contaminating properties; when they contact an acceptable food, they render that food unacceptable. The offensiveness of certain foods expands to the offensiveness of any reminders of the animal nature of humans, especially death and its odor of decay. Further expansions include interpersonal disgust; direct or indirect contact with undesirable people or simply strangers, and moral disgust, directed at certain types of moral violations. An alternative recent view categorizes disgust elicitors, based on evolutionary considerations, into pathogen avoidance, avoidance of certain sexual contacts, and avoidance of a wide range of moral violations. The elicitors and meanings of disgust vary across time and culture, with interpersonal and moral disgust expressed particularly prominently in Hindu India. Disgust has been transformed, in human cultural evolution, into an emotion that promotes withdrawal from a wide range of culturally unacceptable entities; it is a major force in socialization, and may have become a guardian of the 'soul,' as well as the body.

Disgust appears as a fundamental emotion in sources as different as ancient Hindu texts and Darwin's (1965/1872) *The Expression of the Emotions in Man and Animals*. Although usually listed as one of six basic emotions in modern psychology texts, disgust was virtually unexplored until the last 20 years. In the last 20 years, disgust has received much attention in psychology and other disciplines; there were only a few books ever written about disgust before 2010; at least five have appeared since 2010 (note particularly Herz, 2011; Kelly, 2011).

Darwin defined disgust as referring to "something revolting, primarily in relation to the sense of taste, as actually perceived or vividly imagined; and secondarily to anything that causes a similar feeling, through the sense of smell, touch and even of eyesight" (p. 253). In the classic psychoanalytic treatment of disgust, Andras Angyal (1941) claimed that "disgust is a specific reaction toward the waste products of the human and animal body" (p. 395). Angyal related the strength of disgust to the degree of intimacy of contact, with the mouth as the most sensitive focus. Sylvan Tomkins (1963) has offered the more general contention that disgust is "recruited to defend the self against psychic incorporation or any increase in intimacy with a repellent object" (p. 233). Derivative of Angyal's definition, Rozin and Fallon (1987, p. 23) expand on Angyal's definition, and define disgust as: "Revulsion at the prospect of (oral) incorporation of an offensive object. The offensive objects are contaminants; that is, if they even briefly contact an acceptable food, they tend to render that food unacceptable." Disgust is related to pollution, as used in the anthropological literature. In particular, Mary Douglas' (1966) view of polluting meaning matter out of place has direct relevance to disgust.

Most scholars recognize a special relation between disgust and ingestion: the facial expression of disgust represents an oral and nasal 'rejection,' the word 'disgust' in English and some other languages means 'bad taste,' and nausea, the physiological signature of disgust, is directly related to, and inhibitory of, ingestion.

However, it is also clear that, cross-culturally, the emotion of disgust is elicited by a wide range of elicitors, most of which have nothing to do with food. The history and trajectory of disgust, from a food-related emotion to a much more general emotion, is the central concern of this article.

Disgust as an Emotion

Disgust is the only basic emotion that is specifically related to a motivation (hunger) and to a particular bodily location (mouth). Along with other basic emotions, as described by Paul Ekman (1992), disgust has a characteristic behavior (withdrawal), physiological state (nausea), and facial expression (see also Izard, 1971). The facial expression centers on the mouth and nose, and is characterized principally by a wrinkling of the nose, a raising of the upper lip, and a gape. There are also characteristic bodily gestures. The mental or feeling component of disgust is often described as revulsion.

The Meaning of Disgust

Rozin et al. (1993, 2008), based on surveys in Japan and the United States, designate nine domains of disgust: certain foods or potential foods, body products, animals, sexual behaviors, contact with death or corpses, violations of the exterior envelope of the body (including gore and deformity), poor hygiene, interpersonal contamination (direct or indirect contact with unsavory human beings), and certain moral offenses. A more recent formulation by Tybur and colleagues, based in part on

evolutionary considerations, organizes the wide range of disgust elicitors into three groups, pathogen avoidance (which includes potentially all of the previously listed elicitors except sexual and moral), sexual violations, and moral violations (Tybur et al., 2013). Disgust has to do with offensive things; these are wide in range, but exclude many other types of negative events, such as pain, and those that elicit the emotions of fear, sadness, and anger.

Rozin et al. (1993, 2008) propose that disgust originated in animals as a response to distasteful food, and others have added to this origin a set of adaptations to avoidance of pathogens. These authors hold that in cultural evolution, the output side of disgust (expression, physiology, behavior) remained relatively constant, but the range of elicitors and meanings expanded dramatically. The meaning of disgust became offensiveness to the self or soul, rather than bad taste, its origin. Indeed, it was proposed that, in humans, distasteful items do not elicit the full emotion of disgust. The expansion of elicitors and meanings in cultural evolution was attributed to the process of preadaptation; use of a mechanism evolved in one system for a novel use in another system. For example, the mouth, and in particular the teeth and tongue, evolved for processing food, but these structures were co-opted in human evolution for use in speech articulation. The expansion of the meanings of disgust is proposed to have occurred in four stages.

Core Disgust

Core disgust, the initial form of disgust, and the form that appears first in children, has to do with food, but primarily the nature and origin of the food, rather than its taste (Rozin and Fallon, 1987). Core disgust has three components: (1) a sense of oral incorporation (and hence a linkage with food or eating); (2) a sense of offensiveness; and (3) contamination potency. The mouth is the principal route of entry of material things into the body; such things may be essential for life, but may also be very harmful. Disgust has to do with the harmful side, the risks of ingestion. The threat of oral incorporation is illustrated by a widespread belief that "You are what you eat." As others (e.g., Tybur et al., 2013; Oaten et al., 2009; Schaller and Park, 2011) have noted, many of the features of core (and much of animal reminder) disgust can be understood as adaptations to avoidance of pathogens.

Almost all elicitors of core disgust are potential foods that are whole animals, or animal body parts or body products. The great majority of food taboos concern animals and their products, and in most cultures the great majority of animals as potential foods are considered disgusting.

The contamination response (e.g., the rejection of a potential food if it even briefly contacted a disgusting entity) appears to be powerful and universal among adults, and is a defining feature of disgust. It is an example of the sympathetic magical law of contagion, which essentially holds that "once in contact, always in contact" (Rozin and Nemeroff, 1990). It has an obvious adaptive value as part of a pathogen avoidance system.

Animal Reminder Disgust

Common elicitors of disgust include inappropriate sex, poor hygiene, death, and violations of the ideal body envelope (e.g., gore, deformity, obesity). Contact with death and the odor of death (decay) are potent elicitors of disgust. Individuals who score high on disgust sensitivity also score higher on a fear of death scale.

The centrality of death in disgust suggests a more general construal of disgust. Disgust may be understood as a defense against a universal fear of death. Ernst Becker has argued that the most important threat to the psyche is the certainty of death. Human beings are the only organisms that know they will die. Disgust, as a withdrawal system, may help to suppress thoughts or experiences that suggest human mortality.

More generally, anything that reminds us that we are animals may disgust us (Rozin and Fallon, 1987). Disgust serves to 'humanize' our animal bodies. Eating, excretion, sex, soiling of the body surface, soft viscera within the body envelope, and death are all properties that humans share with animals. Cultures typically have extensive rules about these matters, including a wide range of prohibitions. People who ignore these prescriptions are reviled as disgusting and animal-like. This conception of disgust links it to the concern of humans, frequently cited by anthropologists, to distinguish themselves from animals. It has recently been suggested that the wide range of core and animal-reminder elicitors (and interpersonal disgust) can be grouped into one larger category, as a pathogen avoidance system (Tybur et al., 2013).

Interpersonal and Moral Disgust

Across cultures, there is a sense of disgust at touching most people who are not intimates, of making indirect contact with them, such as by wearing their clothing. Most other persons are contaminating, in this sense, and this sensitivity can serve to reinforce social boundaries (or as a pathogen avoidance mechanism). Cultures differ in degree of this sensitivity; it is particularly high in Hindu India, where it serves as an important means of maintaining caste distinctions.

In many, if not all languages, the word for 'disgust' is applied to certain moral violations, and the contamination property of disgust is also extended to the perpetrators of such immoral acts. It is possible that disgust functions, along with anger and contempt, as a basic moral emotion involved in expressing moral outrage at the actions of another. Richard Shweder et al. (1997) identify three types of moral codes that occur in cultures around the world. Violation of the community code, having to do with issues of hierarchy and duty, may map on to the emotion of contempt. Violations of the autonomy code deal with rights and justice, and may be associated with anger. The third code, divinity, focuses on the self as a spiritual entity and seeks to protect that entity from degrading or polluting acts. Disgust may be the emotion that is evoked when the divinity code is violated (Rozin et al., 1999). A more modern formulation of disgust categorizes the interpersonal and moral elicitors of disgust into two categories, sexual (mate selection) and generally moral (including potentially all moral violations) (Tybur et al., 2013). There is certainly evidence that Americans apply the word 'disgusting' to a wide range of moral violations; the question is whether this is a metaphoric and very general use of the word, or implies a specific link between disgust and a wide range of moral violations.

Development of Disgust

Distaste, the origin of disgust, is present at birth, as in the innate rejection by neonates of bitter substances. Disgust, with contamination sensitivity as a defining feature, first appears in North American children at about 4 or 5 years of age. Disgust, as opposed to distaste, seems to be uniquely human, and is entirely or primarily a product of culture. The contamination response, also uniquely human, is probably, in origin, a means of protection from microbial contamination; however, it is acquired. Even feces, surely a source of such contamination and a universal disgust substance among human adults, are not rejected by infants. Toilet training may well be the first disgust-generating experience for humans, but the means by which strong negative affect becomes associated with feces is unknown, as is the way that disgust 'spreads' to a wider range of elicitors. Presumably, parental reactions to disgusting things play a central role in the development of disgust. There is evidence for family resemblance in disgust sensitivity. Although the evidence is not yet strong, it appears that core (or pathogen) disgust appears before the other types of disgust.

Disgust, History and Culture

Across cultures and history, the expression of disgust seems to vary rather little, while the elicitors and meanings vary widely. It seems that disgust was relatively infrequent and limited to a narrow range of elicitors in medieval Europe. The full scope of disgust in Western history, and its flowering as both an emotion of sensibility to the animal nature of humans and a marker of immorality is presented in William Miller's (1997) *Anatomy of Disgust*.

Many cultures show specific attractions to entities that most other cultures find disgusting. For example, particular spoiled foods (e.g., cheese for the French, fermented fish sauce for Southeast Asians) are highly desired in particular cultures, and there are major differences in the sexual practices and contact with the dead across cultures.

The largest historical and cultural variation in disgust is probably associated with interpersonal and moral disgust. For example, disgust seems to center more on interpersonal and moral matters for Hindu Indians than it does for Americans.

Individual Differences

Results from a standardized test of disgust sensitivity, applied in Japan and the United States, indicate that sensitivity is somewhat higher in females and people of lesser education or lower social class (Haidt et al., 1994; Olatunji et al., 2007). A more recent measure of individual differences in disgust has been developed by Tybur et al. (2009). As well, disgust has been implicated in two clinical phenomena: phobias and obsessive compulsive disorder.

Neural Correlates of Disgust

There has been extensive recent work on the neural basis or correlates of disgust. Evidence suggests that an area activated when disgust is experienced is the insula, the area with linkages to the olfactory system. There is also some evidence for common activation of brain areas in response to elicitors as different as core (pathogen-linked) entities and moral violations.

Disgust and Related Emotions

Fear and disgust share a behavioral component, withdrawal based on a threat. Anger and sociomoral disgust share the appraisal of moral condemnation and the common facial gesture of raised upper lip. Contempt shares the appraisal that someone is base and inferior to oneself, but has a complex and rich set of connotations. Shame has been described as disgust turned inward, a judgment that the self is disgusting. It is not clear what emotion is 'opposite' to disgust, but perhaps love is the closest opposite.

Disgust and the Arts

Disgusting images appear frequently in visual art. Disgust is also a focus of humor, at least in Western culture, and plays a particularly central role in children's humor. Disgust appears to be attractive in situations where it is contained and not too threatening; in this regard, our enjoyment of disgust may be related to our enjoyment of horror movies, sad movies, and amusement park rides. All of these proclivities seem to be uniquely human. In general, disgust plays a major role in socialization and the sensibilities it promotes are at the heart of what it means to be human and to be civilized.

Disposable Youth in America in the Age of Neoliberalism

Henry A Giroux, McMaster University, Hamilton, ON, Canada; and Ryerson University, Toronto, ON, Canada

© 2015 Elsevier Ltd. All rights reserved.

Abstract

With the rise of market fundamentalism, today's youth are facing a crisis unlike that of any other generation. Young people, especially poor minority youth, are no longer seen as a social investment but as a problem and, in some cases, 'disposable.' Caught between the discourses of consumerism and a powerful crime-control complex, young people are either viewed increasingly as commodities or are subjected to the dictates of an ever expanding criminal justice system. I explore the current conditions of young people and their everyday experiences within an emerging governing-through-crime complex, the neoliberal politics of disposability, and the ever-present market-driven forces of privatization and commodification. I focus on the contemporary United States as the prime example of a country that is disposing of its youth. I also raise some important questions regarding the role that youth, in particular, might play in challenging the what might be called the crisis of disposability in the age of late modernity, while deepening and extending the promise of an aspiring democracy.

Since the 1970s, there has been an intensification of the anti-democratic pressures of market-driven modes of governance, ideology, and policies around the world, but perhaps most vividly seen in the United States. While many 'crises of youth' have occurred across the sweep of time, what is new in this historical conjuncture is the way in which young people, particularly low-income and poor minority youth, are increasingly denied any place in an already weakened social contract and the degree to which they are no longer seen as central to how the United States defines its future. Youth are no longer the age-group in which American society reveals its dreams but is instead where it hides its nightmares. Within neoliberal narratives, youth are either defined as a consumer market or they stand for trouble and are 'disposable,' not worthy of investment (Grossberg, 2005; Giroux, 2009). This shift in representations of how American society talks about young people betrays a great deal about what is increasingly novel about the economic, social, cultural, and political constitution of American society and its growing disinvestment in young people, the social state, and democracy itself (Comaroff and Comaroff, 2006).

Disposability now defines the fate of those young people who are seen as flawed consumers, excess, or 'othered' as result of their class or race. Relegated to 'zones of abandonment' (Biehl, 2005) and social death, ranging from underfunded schools to the criminal justice system, youth have become a marker for a mode of disposability in which their fate is defined largely through the registers of a society that throws away resources, people, and goods. Within these zones of abandonment and social death, poor minority and low-income youth are viewed as out of step, place, and time and defined largely as 'pathologies feeding on the body politic' relegated to spheres of 'terminal exclusion' (Biehl, 2005: p. 14).

The promises of modernity regarding progress, freedom, and hope have not been eliminated; they have been reconfigured, stripped of their emancipatory potential, and relegated to the logic of a savage market instrumentality. Modernity has reneged on its promise, however disingenuous or limited, to young people of mobility, stability, and collective security. Long-term planning and the institutional structures that support them are now relegated to the imperatives of privatization, deregulation, flexibility, and short-term investments. Social bonds have given way under the collapse of social protections and the welfare state just as "the emphasis is now on individual solutions to socially produced problems" (Bauman, 2007: p.14). As Sharon Stephens points out, what we are now witnessing is not only the "wide-ranging restructurings of modernity" but also the effect "these changes have for the concept of childhood and the life conditions of children" (1995: p. 19).

Zygmunt Bauman argues that today's youth have been "cast in a condition of liminal drift, with no way of knowing whether it is transitory or permanent" (Bauman, 2004: p. 76). The severity of the consequences of this shift in modernity under neoliberalism among youth is evident in the fact that this is the first generation in which the "plight of the outcast may stretch to embrace a whole generation" (Bauman, 2012a; developed further in Bauman, 2012b, 2012c). That is, the generation of youth in the early twenty-first century has no way of grasping if they will ever "be free from the gnawing sense of the transience, indefiniteness, and provisional nature of any settlement" (Bauman, 2004: p. 76). Neoliberal violence produced in part through a massive shift in wealth to the upper 1%, growing inequality, the reign of the financial services, the closing down of educational opportunities, and the stripping of benefits and resources from those marginalized by race and class has produced a generation without jobs, an independent life, and even the most minimal social benefits.

Youth no longer occupy the hope of a privileged place that was offered to previous generations. They now inhabit a neoliberal notion of temporality marked by a loss of faith in progress along with the emergence of apocalyptic narratives in which the future appears indeterminate, bleak, and insecure. Heightened expectations and progressive visions pale and are smashed next to the normalization of market-driven government policies that wipe out pensions, eliminate quality health care, raise college tuition, and produce a harsh world of joblessness, while giving millions to banks and the military. Students, in particular, now find themselves in a world in which heightened expectations have been replaced

 http://dx.doi.org/10.1016/B978-0-08-097086-8.64123-5

by dashed hopes and a world of onerous debt (Fraser, 2013). The promises of higher education and previously enviable credentials have turned into the swindle of fulfillment as "For the first time in living memory, the whole class of graduates faces a high probability, almost the certainty, of ad hoc, temporary, insecure and part-time jobs, unpaid 'trainee' pseudo-jobs deceitfully rebranded 'practices' – all considerably below the skills they have acquired and eons below the level of their expectations" (Bauman, 2012b: p. 47).

What has changed about an entire generation of young people includes not only neoliberal society's disinvestment in youth and the permanent fate of downward mobility, but also the fact that youth live in a commercially carpet-bombed and commodified environment that is unlike anything experienced by those of previous generations. Nothing has prepared this generation for the inhospitable and savage new world of commodification, privatization, joblessness, frustrated hopes, surveillance, and stillborn projects (Bauman, 2012b: p. 47). The present generation has been born into a throwaway society of consumers in which both goods and young people are increasingly objectified and disposable.

That is, young people are viewed as excess, a drain on the body politic, part of a throwaway society, and unworthy of long-term investments. In this discourse, young people are not troubled but trouble; rather than viewed as at risk, they are the risk and subject to a range of punitive policies. As Larry Grossberg points out, young people now inhabit a world in which there are few public spheres or social spaces autonomous from the reach of the market.

> Kids see themselves presented in highly sexualized ways for advertising and entertainment purposes, even while their own sexual behavior is repressed and criminalized. … kids hear themselves attacked for their consumerism, even while the media and corporate interests commercialize and commodify every dimension of their lives, every pleasure, every need. From the kids' perspective, it looks as if we are selling, or perhaps we already have sold, our children to advertisers, to private business, to corporate capitalism. … What can it say to them that as a society we are unwilling to pay for their education (as ours had been paid for) but we are willing to commercialize education (junk foods, field trips to chain stores, sponsored lesson materials and textbooks, advertising in hallways). (2005: pp. 38–39)

The structures of neoliberal modernity do more than disinvest in young people and commodify them, they also transform the protected space of childhood into a zone of disciplinary exclusion and cruelty, especially for those young people further marginalized by race and class who now inhabit a social landscape in which they are increasingly disparaged as flawed consumers. With no adequate role to play as consumers, many youth are now considered disposable, forced to inhabit 'zones of social abandonment' extending from bad schools to bulging detention centers and prisons (Biehl, 2005). These are zones where not only the needs of young people are ignored, but they are subjected to conditions of impoverishment and punishment that underserve them and often criminalize their behavior. For example, with the hollowing out of the social state and the rise of the punishing state, the circuits of state repression, surveillance, and disposability increasingly 'link the fate of Blacks, Latinos, Native Americans, poor Whites, and Asian-Americans' who are now caught in a governing through crime youth complex that now serves as default solutions to major social problems (Davis, 2007).

This radical neoliberal shift in modernity becomes evident as economic power succeeds in detaching itself from government regulations, social costs, and ethical considerations, a new global financial class reasserts the prerogatives of capital and systemically destroys those public spheres – including public and higher education – that traditionally advocated for social equality and an educated youth as the fundamental conditions for a viable democracy. Power is now global and politics is local, inhabited by eviscerated state governments and a weakened nation-state. Stripped of their power, state governments have few resources to devote to the genuine causes of people's hardships, suffering, and socially produced problems. Increasingly, they function as an adjunct of financial interests and exercise power through the varied apparatuses of the punishing state. Since September 2011, the paralyzing fog of depoliticization has been ruptured by the intermittent roar of angry workers, and of young people who refuse to cede their future to the new oligarchs, bankers, conservative think tanks, hedge fund managers, Christian extremists, and the corporate-controlled liberal and conservative media apparatuses.

Disposable Youth, Violence, and Corporate Power

Disposability has become not only a register for neoliberal domination but also a mark of refusal and growing resistance on the part of young people from New York City to Athens, Greece who remind us that the possibility of collective struggle and shared hopes is far from a lost moment in history (Hardt and Negri, 2012; Castells, 2012; Giroux, 2013a). Young people are demonstrating across the world against a variety of issues ranging from economic injustice and massive inequality to drastic cuts in education and public services. Refusing to inhabit the stateless position of disposable populations, young people are fighting back, but not without resistance on the part of established countries caught in the grip of neoliberal austerity measures. These demonstrations are being met with state-sanctioned violence and insults in the mainstream media rather than with informed dialogue, critical engagement, and reformed policies. In the United States, Chile, Brazil, Mexico, and many other countries the state monopoly on the use of violence has intensified since the 1980s and in the process has been increasingly directed against young people, poor minorities, immigrants, and increasingly women. As the welfare state is hollowed out, a culture of compassion is replaced by a culture of violence, cruelty, and disposability. Collective insurance policies and social protections have given way to the forces of economic deregulation, the transformation of the welfare state into punitive workfare programs, the privatization of public goods, and an appeal to individual responsibility as a substitute for civic responsibility. Under the notion that unregulated market-driven values and relations should shape every domain of human life, the business model of governance has eviscerated any viable notion of social responsibility while furthering the criminalization of social problems and cutbacks in basic social services, especially for

the poor, young people, and the elderly (Wacquant, 2009). Within the existing neoliberal historical conjuncture, there is a merging of violence and governance and the systemic disinvestment in and breakdown of institutions and public spheres that have provided the minimal conditions for democracy.

Abandoned by the existing political system, young people are placing their bodies on the line, protesting peacefully while trying to produce a new language, politics, long-term institutions, and "community that manifests the values of equality and mutual respect that they see missing in a world that is structured by neoliberal principles" (Bella, 2011). Such movements are not simply about reclaiming space but also about producing new ideas, generating a new conversation, and introducing a new political language. Rejecting the notion that democracy and markets are the same, young people are calling for an end to the corporate control of the commanding institutions of politics and culture, poverty, the suppression of dissent, and the permanent war state. Richard Lichtman is right in insisting that this movement should be praised for its embrace of communal democracy as well as an emerging set of shared concerns, principles, and values articulated "by a demand for equality, or, at the very least, for a significant lessening of the horrid extent of inequality; for a working democracy; for the elimination of the moneyed foundation of politics; for the abolition of political domination by a dehumanized plutocracy; for the replacement of ubiquitous commodification by the reciprocal recognition of humanity in the actions of its agents" (Lichtman, 2011).

While there is considerable coverage in the progressive media given to the violence being waged against the movement protesters in Brazil, the United States, Greece, and elsewhere, it is important to situate such violence within a broader set of categories that enables a critical understanding of not only the underlying social, economic, and political forces at work in such assaults, but also allows us to reflect critically on the distinctiveness of the current historical period in which they are taking place (Giroux, 2013). For example, it is difficult to address such state-sponsored violence against young people without analyzing the devolution of the social state, the politics of disposability, and the corresponding rise of the warfare and punishing state.

The merging of the military–industrial complex and unbridled corporate power in many countries points to the need for strategies that address what is specific about the current warfare state and the neoliberal project and how different interests, modes of power, social relations, public pedagogies, and economic configurations come together to shape its politics. Such a conjuncture is invaluable politically in that it provides a theoretical opening for making the practices of the warfare state and the neoliberal revolution visible in order 'to give the resistance to its onward march, content, focus, and a cutting edge' (Hall, 2011a: p. 706). It also points to the conceptual power of making clear that history remains an open horizon that cannot be dismissed through appeals to the end of history or end of ideology (Bell, 1966; Fukuyama, 2006). It is precisely through the indeterminate nature of history that resistance becomes possible and politics refuses any guarantees and remains open. Following Stuart Hall (2011), I argue that the current historical moment or what he calls the 'long march of the Neoliberal Revolution,' has to be understood in terms of the growing forms of violence that it deploys and reinforces. Such antidemocratic pressures and their relationship to the rising protests of young people in the United States and abroad are evident in the crisis that has emerged through the merging of governance and violence, the growth of the punishing state, and the persistent development of what has been described by Alex Honneth as "a failed sociality" (2009: p. 188).

Too many neoliberal societies, the United States in particular, have become addicted to violence. War provides jobs, profits, political payoffs, research funds, and forms of political and economic power that reach into every aspect of society. As war becomes a mode of sovereignty and rule, it erodes the distinction between war and peace. Increasingly fed by a moral and political hysteria, warlike values produce and endorse shared fears as the primary register of social relations. Shared fears and the media hysteria that feed them produce more than a culture of fear. Such hysteria also feeds the growing militarization of the police who increasingly use their high-tech scanners, surveillance cameras, and toxic chemicals on anyone who engages in peaceful protests against the warfare and corporate state. Images abound in the mainstream media of such abuses.

The war on terror has become a war on democracy as baton-wielding cops are now being supplied with the latest military equipment imported straight from the battlefields of Iraq and Afghanistan. Military technologies once used exclusively on the battlefield are now being supplied to police departments across the nation. Drones, machine-gun-equipped armored trucks, Special Weapons and Tactics (SWAT) vehicles, "digital communications equipment, and Kevlar helmets, like those used by soldiers used in foreign wars" (Becker and Schulz, 2011). The domestic war against 'terrorists' (code for young protesters) provides new opportunities for major defense contractors and corporations who 'are becoming more a part of our domestic lives' (Becker and Schulz, 2011). Arming domestic police forces with paramilitary weaponry will ensure their systematic use even in the absence of a terrorist attack on US soil; they will simply find other, increasingly permissive uses for those weapons (Greenwald, 2011).

As a mode of public pedagogy, a state of permanent war needs willing subjects to abide by its values, ideology, and narratives of fear and violence. Such legitimation is largely provided through a market-driven culture addicted to the production consumerism, militarism, and organized violence, largely circulated through various registers of popular culture that extend from high fashion and Hollywood movies to the creation of violent video games and music concerts sponsored by the Pentagon. The market-driven spectacle of war demands a culture of conformity, quiet intellectuals, and a largely passive republic of consumers. But it also needs subjects who find intense pleasure in the spectacle of violence.

As the pleasure principle is unconstrained by a moral compass based on a respect for others, it is increasingly shaped by the need for intense excitement and a never-ending flood of heightened sensations. What has led to this immunity and insensitivity to cruelty and prurient images of violence? Part of this process is due to the fact that the American public is

bombarded by an unprecedented "huge volume of exposure to … images of human suffering" (Bauman, 1995: p. 149). As Bauman argues, there are social costs that come with this immersion of a culture of staged violence. One consequence is that "the sheer numbers and monotony of images may have a 'wearing off' impact [and] to stave off the 'viewing fatigue,' they must be increasingly gory, shocking, and otherwise 'inventive' to arouse any sentiments at all or indeed draw attention. The level of 'familiar' violence, below which the cruelty of cruel acts escapes attention, is constantly rising" (Bauman, 1995).

Hyperviolence and spectacular representations of cruelty disrupt and block our ability to respond politically and ethically to the violence as it is actually happening on the ground. In this instance, unfamiliar violence such as extreme images of torture and death become banally familiar, while familiar violence that occurs daily is barely recognized relegated to the realm of the unnoticed and unnoticeable. How else to explain the public indifference to the violence waged by the state against nonviolent youthful protesters who are rebelling against a society in which they have been excluded from any claim on hope, prosperity, and democracy. As an increasing volume of violence is pumped into the culture, yesterday's spine-chilling and nerve-wrenching violence loses its shock value. As the need for more intense images of violence accumulates, the moral indifference and desensitization to violence grows while matters of cruelty and suffering are offered up as fodder for sports, entertainment, news media, and other outlets for seeking pleasure.

Marked by a virulent notion of hardness and aggressive masculinity, a culture of violence has become commonplace in a society in which pain, humiliation, and abuse are condensed into digestible spectacles endlessly circulated through extreme sports, reality TV, video games, YouTube postings, and proliferating forms of the new and old media. But the ideology of hardness and the economy of pleasure it justifies are also present in the material relations of power that have intensified across the globe since the 1970s. Conservative and liberal politicians alike now spend millions waging wars around the globe, funding the largest military state in the world, providing huge tax benefits to the ultrarich and major corporations, and all the while draining public coffers, increasing the scale of human poverty and misery, and eliminating all viable public spheres – whether they be the social state, public schools, public transportation, or any other aspect of a formative culture that addresses the needs of the common good. State violence, particularly the use of torture, abductions, and targeted assassinations are now justified as part of a state of exception that has become normalized. A 'political culture of hyperpunitiveness' (Herbert and Brown, 2006) has become normalized and accelerates throughout the social order like a highly charged electric current. Democracy no longer emphasizes the importance of an experience of the common good. Symptoms of ethical, political, and economic impoverishment are all around us.

Meanwhile, exaggerated violence is accelerated in the larger society and now rules screen culture. The public pedagogy of entertainment includes extreme images of violence, human suffering, and torture splashed across giant movie screens, some in 3D, offering viewers every imaginable portrayal of violent acts, each more shocking and brutal than the last. The growing taste for violence can be seen in the increasing modeling of public schools after prisons, the criminalization of behaviors such as homelessness that once were the object of social protections. A symptomatic example of the way in which violence has saturated everyday life can be seen in the growing acceptance of criminalizing the behavior of young people in public schools. Behaviors that were normally handled by teachers, guidance counselors, and school administrators are now dealt with by the police and the criminal justice system. The consequences have been disastrous for young people. Not only do schools resemble the culture of prisons, but young children are being arrested and subjected to court appearances for behaviors that can only be termed as trivial. This is not merely barbarism parading as reform – it is also a blatant indicator of the degree to which sadism and the infatuation with violence have become normalized in a society that seems to take delight in dehumanizing itself.

As the social is devalued along with rationality, ethics, and any vestige of democracy, spectacles of war, violence, and brutality now merge into forms of collective pleasure that constitute an important and new symbiosis between visual pleasure, violence, and suffering. The control society is now the ultimate form of entertainment as the pain of others, especially those considered disposable and powerless, has become the subject not of compassion but of ridicule and amusement. High octane violence and human suffering are now considered another form of entertainment designed to raise the collective pleasure quotient. Reveling in the suffering of others should no longer be reduced to a matter of individual pathology, but now registers a larger economy of pleasure across the broader culture and social landscape. My emphasis here is on the sadistic impulse and how it merges spectacles of violence and brutality with forms of collective pleasure. No society can make a claim to being a democracy as long as it defines itself through shared fears rather than shared responsibilities. Widespread violence now functions as part of an anti-immune system that turns the economy of genuine pleasure into a mode of sadism that creates the foundation for sapping democracy of any political substance and moral vitality.

The predominance of violence in all aspects of social life suggests that young people and others marginalized by class, race, and ethnicity have been abandoned as American society's claim on democracy gives way to the forces of militarism, market fundamentalism, and state terrorism. The prevalence of violence throughout American society suggests the need for a politics that not only negates the established order but imagines a new one, one informed by a radical vision in which the future does not imitate the present (Van Houdt, 2011). In this discourse, critique merges with a sense of realistic hope, and individual struggles merge into larger social movements. The challenge that young people are posing to American society is being met with a state-sponsored violence that is about more than police brutality; it is more importantly about the transformation of the United States from a social state to a warfare state, from a state that embraced the social contract to one that no longer has a language for community – a state in which the bonds of fear and commodification have replaced the bonds of civic responsibility and democratic vision. Until we address how the metaphysics of war and violence have taken hold on

American society (and in other parts of the world) and the savage social costs it has enacted, the forms of social, political, and economic disposability that young people are protesting against as well as the violence waged in response to their protests will become impossible to recognize and act on.

The Politics of Disposable Youth in the United States

The general response from progressives and liberals to the plight of youth, especially poor minorities of color, fails to take seriously the ways in which the extreme right-wing articulates its increasingly pervasive and destructive view of American society. For instance, the views of new extremists in the US Congress are often treated, especially by liberals, as a cruel hoax that is out of touch with reality or a foolhardy attempt to roll back the Obama agenda (Beutler, 2013). On the left, such views are often criticized as a domestic version of the tactics employed by the Taliban – keeping people stupid, oppressing women, living in a circle of certainty, and turning all channels of education into a mass propaganda machine of fundamentalist Americanism. All of these positions touch on elements of a deeply authoritarian agenda. But such commentaries do not go far enough. Tea Party politics is about more than bad policy, policies that favor the rich over the poor, or for that matter about modes of governance and ideology that represent a blend of civic and moral turpitude. The hidden order of neoliberal politics in this instance represents the poison of neoliberalism and its ongoing attempt to destroy those very institutions whose purpose is to enrich public memory, prevent needless human suffering, protect the environment, distribute social provisions, and safeguard the public good. Within this rationality, markets are not merely freed from progressive government regulation, they are removed from any considerations of social costs. And where government regulation does exits, it functions primarily to bail out the rich and shore up collapsing financial institutions and for what Noam Chomsky has termed America's only political party, "the business party" (2008).

In short, within the reigning economic and political order in the United States, youth have been left out of the narrative of democracy. The stories that attempt to cover over America's embrace of historical and social amnesia at the same time justify authoritarianism with a soft edge and weakens democracy through a thousand cuts to the body politic. How else to explain the Obama administration's willingness to assassinate American citizens allegedly allied with terrorists, secretly monitor the e-mail messages and text messages of its citizens, use the National Defense Authorization Act to arrest and detain indefinitely American citizens without charge or trial, subject alleged spies to an unjust military tribunal system, use drones as part of a global assassination campaign to arbitrarily kill innocent people, and then dismiss such acts as collateral damage. As Jonathan Turley points out, "An authoritarian nation is defined not just by the use of authoritarian powers, but by the ability to use them. If a president can take away your freedom or your life on his own authority, all rights become little more than a discretionary grant subject to executive will" (2012). This point seems to be especially true for young people who are one of the most vulnerable groups in society.

At the heart of the oppression experienced by young people are ideologies, modes of governance, and policies that embrace a pathological individualism, a distorted notion of freedom, and a willingness both to employ state violence to suppress dissent and abandon those suffering from a collection of social problems ranging from dire poverty and joblessness to homelessness. In the end, these are stories about disposability in which growing numbers of young people are considered dispensable and a drain on the body politic, the economy, and the sensibilities of the rich and powerful. Rather than work for a more dignified life, most young people now work simply to survive – that is, if they can find work – in a survival of the fittest society in which getting ahead and accumulating capital, especially for the ruling elite, is the only game in town. In the past, public values have been challenged and certain groups have been targeted as superfluous or redundant. But what is new about the politics of disposability that has become a central feature of contemporary American politics is the way in which such antidemocratic practices have become normalized in the existing neoliberal order. A politics of inequality and ruthless power disparities is now matched by a culture of cruelty soaked in blood, humiliation, and misery. Private injuries not only are separated from public considerations such narratives, but narratives of poverty and exclusion have become objects of scorn. Since the 1980s, many conservatives and neoliberals have viewed all noncommercial public spheres where such stories might get heard with contempt, a perfect supplement to the chilling indifference to the plight of the disadvantaged and disenfranchised (see Krugman, 2013, for example).

Any viable struggle against the authoritarian forces that dominate the United States must make visible the indignity and injustice of these narratives and the historical, political, economic, and cultural conditions that produce them. Investing in young people is central in the development of any viable democracy. Such a recognition suggests a critical analysis of how various educational forces in American society are distracting and miseducating the public. Dominant political and cultural responses to current events – such as the ongoing economic crisis, income inequality, health care reform, Hurricane Sandy, the war on terror, the Boston Marathon bombing, and the crisis of public schools in Chicago, Philadelphia, and other cities – represent flash points that reveal a growing disregard for people's democratic rights, public accountability, and civic values. As politics is disconnected from its ethical and material moorings, it becomes easier to punish and imprison young people than to educate them. From the inflated rhetoric of the political right to market-driven media peddling spectacles of violence, the influence of these criminogenic and death-saturated forces in everyday life is undermining our collective security by justifying cutbacks to social supports and restricting opportunities for democratic resistance. Saturating mainstream discourses with antipublic narratives, the neoliberal machinery of social death effectively weakens public supports and prevents the emergence of much needed new ways of thinking and speaking about politics in the

twenty-first century. But even more than neutralizing collective opposition to the growing control and wealth of predatory financial elites – that wield power across all spheres of US society – responses to social issues are increasingly dominated by a malignant characterization of marginalized groups as disposable populations. As I have mentioned above, all the while zones of abandonment accelerate the technologies and mechanisms of disposability. One consequence is the spread of a culture of cruelty in which human suffering is not only tolerated, but viewed as part of the natural order of things (Giroux, 2012, 2013).

From the Politics of Cruelty to the Politics of Civic Engagement

The notion of a culture of cruelty is useful in thinking through the convergence of everyday life and politics, of considering material relations of power – the disciplining of the body as an object of control – on the one hand, and the production of cultural meaning, especially the co-optation of popular culture to sanction official violence, on the other. The culture of cruelty is important for thinking through how life and death now converge in ways that fundamentally transform how we understand and imagine politics in the current historical moment – a moment when the most vital of safety nets health care reform is being undermined by right-wing ideologues. Evidence of such cruelty can be seen in attempts on the part of the Republican Party led House of Representatives to eliminate $40 billion dollars from the food stamp program. It is also evident in a range of policies advocated by right-wing extremists in Congress who refuse to raise the minimum wage and extend unemployment benefits for the long-term unemployed.

Before this dangerously authoritarian mind-set has a chance to take hold of our collective imagination and animate our social institutions, it is crucial that all Americans think critically and ethically about the coercive forces shaping US culture – and focus our energy on what can be done to change them. It will not be enough only to expose the falseness of the stories we are told. Educators, progressives, artists, intellectuals, youth, and workers also need to create alternative narratives about what the promise of democracy might be for our children and ourselves. This vision will require a break from established political parties, the creation of alternative public spheres in which to produce democratic narratives and visions, and a notion of politics that is educative, one that takes seriously how people interpret and mediate the world, how they see themselves in relation to others, and what it might mean to imagine otherwise in order to act otherwise. Why are millions not protesting in the streets over these barbaric policies that deprive them of life, liberty, justice, equality, and dignity? What are the pedagogical technologies and practices at work that create the conditions for people to act against their own sense of dignity, agency, and collective possibilities? Progressives and others need to make education central to any viable sense of politics so as to make matters of remembrance and consciousness central elements of what it means to be critical and engaged citizens.

There is also a need for social movements that invoke stories as a form of public memory, stories that have the potential to move people to invest in their own sense of individual and collective agency, stories that make knowledge meaningful in order to make it critical and transformative. If democracy is to once again inspire a populist politics, it is crucial to develop a number of social movements in which the stories told are never completed, but are always open to self- and social reflection, capable of pushing ever further the boundaries of our collective imagination and struggles against injustice wherever they might be. Only then will the stories that now cripple our imaginations, politics, and democracy be challenged and hopefully overcome. Only then will young people be able to recognize themselves in the stories through which America defines itself.

Dispute Resolutions in Economics

Abstract

Negotiation is common in many settings. A common feature of all negotiation is an understanding by the parties to the negotiation about the process that will be used to resolve a dispute in the event the parties fail to reach agreement. The dispute settlement process defines the expectations that the parties have about what will happen in the event that no agreement is reached. This process, in turn, determines negotiator behavior. There are two fundamental types of dispute settlement mechanisms in the labor area: strikes and arbitration. Strikes involve the systematic imposition of costs on each side. Military disputes are implied, but presumably one or both parties concede sufficiently to make an agreement possible and end the dispute. Arbitration involves the mandating of a settlement by a third party. Litigation of civil disputes is another example of this type of mechanism. Several models of strikes and arbitration are outlined. The role of incomplete information and uncertainty are discussed in the context of these models.

Negotiation is common in many settings. A common feature of all negotiation is an understanding by the parties to the negotiation about the process that will be used to resolve a dispute in the event that the parties fail to reach agreement. Disputes between labor unions and employers can end in a strike, or can be resolved by arbitration. Disagreement over contracts or tort damages can result in civil litigation and a decision by a judge or jury. Disagreement between nations can result in military disputes. The dispute settlement process defines the expectations that the parties have about what will happen in the event that no agreement is reached. And this process, in turn, determines negotiator behavior.

There are two fundamental types of dispute settlement mechanism. The first is the systematic imposition of costs on each side. Strikes and military disputes are examples of this type of mechanism. No determinate end to the dispute is implied, but presumably one or both parties concede sufficiently to make an agreement possible and end the dispute. The second mechanism is the mandating of a settlement by a third party. Arbitration of labor and commercial disputes, and litigation of civil disputes, are examples of this type of mechanism.

Both types of mechanism (strikes and arbitration) are used in the resolution of labor disputes, and the discussion here focuses on that area. This discussion is necessarily selective and is meant to provide a brief introduction to important concepts and issues. See Hirsch and Addison (1986) for a more extensive survey.

Strikes

A difficult problem in the economics of labor unions is the modeling of strikes. The difficulty arises because strikes appear to be nonequilibrium phenomena. Both sides would have been better-off if they had been able to agree on whatever the outcome was without bearing the costs of a strike. In other words, strikes are Pareto-dominated by the same bargaining outcome without a strike. While research on strikes in the United States has diminished with the level of strike activity in the USA since the mid-1980s, there was an active empirical literature in the 1970s and 1980s.

Ashenfelter and Johnson (1969) developed a nonequilibrium model of strike activity by attributing to the union an arbitrary concession schedule positing an inverse relationship between the minimum acceptable wage and the length of strike. The firm selects the point on this schedule that maximizes profits, the trade-off being longer strikes involving larger up-front strike losses, but lower labor costs into the future. Ashenfelter and Johnson used this model to motivate an empirical analysis of the aggregate level of strike activity in the United States. Farber (1978) used the same theoretical framework to estimate a structural model of the joint determination of wage changes and strike length using data on the outcomes of a time series of cross-sections of negotiations for large US corporations.

Tracy (1986) developed an equilibrium model of strikes based on learning in a model of asymmetric information (Fudenberg and Tirole, 1981; Sobel and Takahashi, 1983). The model is based on the idea that the union does not know the profitability of the firm. The union would like to extract a high wage from high-profit firms and a lower wage from low-profit firms. The key is that high-profit firms have a high cost of bearing strikes relative to low-profit firms. In this case, the union can make a high initial wage demand. High-profit firms will prefer to pay this wage immediately rather than to lose profits during a strike. Low-profit firms will prefer to lose their lower profits during the strike in exchange for a lower wage into the future.

Tracy (1986) used this model to generate the empirical implication that there will be more strikes where there is more uncertainty about the firm's profitability. He then implemented this model using data on a large number of negotiations and using the volatility of daily stock returns as his measure of uncertainty about profitability. He finds evidence that uncertainty is correlated positively with strike activity. A final point is that the declining concession schedule in the Ashenfelter–Johnson model can be interpreted as a reduced-form expression of the union learning function. As the strike goes on, the union is willing to accept a lower wage as they learn that the firm is lower profit.

It is quite possible that strikes are not equilibrium phenomena, and that the insistence in the economics literature,

both theoretical and empirical, on equilibrium explanations, is inappropriate. Strikes can result from miscalculation. In particular, the parties may be relatively optimistic about the outcome after a strike. For example, the union may expect a wage settlement of \$20 h^{-1} after a strike, while the firm expects to pay only \$18 h^{-1} after the same strike. If the cost of a strike is \$0.50 h^{-1} to each side, then the union will accept no less than \$19.50 to avert the strike, while the firm will be willing to offer no more than \$18.50. The result will be a strike. Of course, the expectations of both sides cannot be accurate, *ex post*. This relative optimism can have a variety of sources. One possibility with a long history in the industrial relations literature, is that the parties selectively overweight arguments that are favorable to their side (Walton and McKersie, 1965; Neale and Bazerman, 1991). However, relative optimism can be generated even with appropriate weighting of available information. If each side is getting independent (and accurate in expectation) information on the likely uncertain outcome, for some fraction of the time the information will lead to relatively optimistic expectations sufficient to outweigh the costs of a strike. Strikes will occur in these cases.

Arbitration

In the United States, arbitration is used commonly to determine the terms of labor contracts in the public sector in cases where the parties cannot agree on their own. In conventional arbitration, the arbitrators are free to impose whatever settlements they deem appropriate. A common alternative is final-offer arbitration, where the arbitrator must select one of the final offers submitted by the parties and cannot compromise.

Conventional Arbitration

Consider the following simple model of the negotiation process where conventional arbitration is the dispute settlement mechanism (Farber and Katz, 1979). Suppose the parties are negotiating over the split of a pie of size one. The share of the pie going to the union is Y, and the share going to the firm is $(1 - Y)$. The arbitrator will impose a settlement of Y_a, and each party has a prior distribution on Y_a. Let Y_a^u and Y_a^f represent the prior expected value to the union and firm, respectively, of the arbitration award. Finally, let C_u and C_f represent the cost to the union and the firm of using arbitration (denominated in pie shares). Assume further that the parties are risk neutral, so that the union will prefer any negotiated share for itself (Y_n) such that $Y_n > Y_a^u - C_u$ and the firm will prefer any negotiated share for itself such that $1 - Y_n > 1 - Y_a^u - C_f$. These are the reservation values of the parties in negotiation. The result is a *contract zone* of settlements preferred by both sides to arbitration that consists of all shares that fall in the range:

$$Y_a^u - C_u < Y_n < Y_a^f + C_f \qquad [1]$$

The size of the contract zone is:

$$CZ = Y_a^f - Y_a^u + C_u + C_f \qquad [2]$$

In the simplest model, there will be a negotiated settlement whenever $CZ \geq 0$, and there will be an arbitrated outcome whenever $CZ < 0$.

This model provides an important insight into when one might expect a dispute. Relative optimism about the likely arbitration award ($Y_a^u > Y_a^f$) can be a reason for a dispute. If the relative optimism is sufficiently great to outweigh the total costs of arbitration ($C_u + C_f$), then there will be no contract zone, and arbitration will be required. Thus, relative optimism is a cause of disputes. Clearly, higher total costs of arbitration imply a larger contract zone. Larger costs make it less likely that any degree of relative optimism will cause there to be no contract zone. Thus, larger total costs of disputing reduce the likelihood of disputes. This latter property is implied by any reasonable model of disputes.

The model also demonstrates how the dispute settlement mechanism determines fundamentally negotiated outcomes. Consider the case where the parties have identical expectations about the arbitration award of $Y_e = Y_a^u = Y_a^f$. The size of the contract zone in this case is determined entirely by the costs of arbitration (eqn [2]), and there will be no dispute. The negotiated settlement will lie in the range defined by:

$$Y_e - C_u < Y_n < Y_e + C_f \qquad [3]$$

In other words, the negotiated settlement will lie in some range around the common expectation of the arbitration award.

One criticism of conventional arbitration as a dispute settlement mechanism in labor disputes is that arbitrators appear to split the difference between the demands of the parties, resulting in an arbitration award that is close to the average of the demands. However, eqn [3] makes it clear that the opposite is likely to be true: The negotiated settlement is likely to lie between the reservation values of the parties. Mnookin and Kornhauser (1979) and Farber (1981) present analyses that make this point.

Final-Offer Arbitration

The perception that arbitrators split the difference in conventional arbitration led to the belief that conventional arbitration 'chilled' bargaining by providing the parties with an incentive to maintain extreme demands. This led to the development of final-offer arbitration, which prevented the arbitrator from compromising (Stevens, 1966). Farber (1980) developed a simple model of final-offer arbitration where arbitrators select the offer closest to what they would have imposed in conventional arbitration (Y_a). In this model, the probability that the union's offer is selected is:

$$P_u = Pr\left(Y_a > \frac{Y_u + Y_f}{2}\right) = 1 - F\left(\frac{Y_u + Y_f}{2}\right) \qquad [4]$$

where Y_u and Y_f represent the final offers of the union and the firm, respectively, and $F(\cdot)$ represents the cumulative distribution function of the parties' common prior on Y_a.

Assuming risk neutrality, the expected payoff to the union from final-offer arbitration is:

$$V_u = P_u Y_u + (1 - P_u) Y_f \qquad [5]$$

and the expected payoff to the firm is:

$$V_f = 1 - \left[P_u Y_u + (1 - P_u) Y_f\right] \qquad [6]$$

The Nash equilibrium final offers of the parties are the offers such that (1) Y_u maximizes V_u conditional on Y_f, and (2) Y_f maximizes V_f conditional on Y_u. These offers have the property that neither party will desire to change its offer.

Since the parties are uncertain about Y_a, the Nash equilibrium final offers reflect a trade-off between the value to the party of its offer if its offer is selected, and the probability that its offer is selected. A more extreme offer yields a higher payoff to the party if its offer is selected by the arbitrator, but it lowers the probability that the offer will be selected.

A key implication of this model is that final-offer arbitration may not encourage more convergence in negotiation than conventional arbitration because of the desire to present optimal final offers to the arbitrator that may be extreme.

Empirical Evidence

Ashenfelter and Bloom (1984) present evidence from arbitration of contract disputes for public sector employees in New Jersey, where both conventional and final-offer arbitration are used, consistent with the general model of arbitrator behavior outlined here. They find that arbitrators use a common underlying notion of Y_a to make awards in both conventional and final-offer arbitration. Their evidence is consistent with the arbitrators' decision in final-offer arbitration being to select the offer closest to Y_a. Bazerman and Farber (1986) reach similar conclusions based on evidence from arbitration awards, both conventional and final-offer, made by professional arbitrators in hypothetical cases.

Convincing evidence is scarce on whether final-offer arbitration leads to more settlements and reduces reliance on arbitration. Ashenfelter et al. (1992) present experimental evidence that does not show higher rates of agreement in final-offer arbitration than in conventional arbitration.

Abstract

Dispute transformation involves the study of how a problem that could be defined as an injury or grievance takes shape over time as a public conflict by the involvement of others (supporters, lawyers, and third parties of various kinds). The process of transformation involves negotiation over framing, which may narrow or expand a conflict in ways that tend to advantage certain interests over others. In this way, changes in the form or content of disputes link dispute management to the ways law and other normative orders are created, maintained, and sometimes challenged or transformed.

Introduction

The 'social construction' of disputes refers to the process by which a subjectively perceived injury or injustice is articulated as a grievance and asserted as a claim before a third party. Disputes are not concrete entities or objective events, but instead take shape over time as a result of the involvement of other participants. 'Transformation of disputes' refers to the change in form or content of a perceived injury or wrong as a result of this involvement, as expressed through language and actions, according to available categories and institutional practices.

Key contributions of the dispute transformation perspective include psychological insight into the perception and assertion of grievances by individual actors; sociological analysis of the distribution of grievances, claims, and court cases for different types of injuries or problems; anthropological study of the way cultural and legal 'dispositions' or 'consciousness' influence conflict management; political science research on how legal institutions and actors shape the perception and construction of claims and grievances; and legal studies of the normative and doctrinal consequences of reframing of disputes. Understanding how disputes emerge and are transformed links a microanalysis of the experience of and response to injury or trouble with a macroview of law, political order, and change.

Law and Disputing

Empirical research on dispute transformation developed in the late 1970s and early 1980s as a result of trends in several social science fields and in law. Anthropologists showed how a focus on 'trouble cases' could provide a useful framework for comparative study of law in different societies. Research reported in Nader and Todd (1978), for example, explored the factors behind parties' choices of different methods for pursuing, or attempting to resolve, trouble cases in diverse societies. Relations between those involved in a case, the location, and the nature of the problem, along with the range of alternatives for pursuing it, could all explain the construction and handling of what might become a public dispute. The interest of anthropologists at the time in actor choices and the availability of different alternatives for conflict management overlapped with the interest of legal scholars in access to justice.

Expansion of legal services for litigants in civil cases and concern for the role of civil courts in society led analysts to examine the legal needs of citizens. What kinds of cases and what groups of citizens are and are not being served by the civil justice system? How can access to justice be improved? Questions such as these spurred efforts to describe and count 'unmet legal needs' in the United States (Curran, 1977) and in the United Kingdom (Genn, 1999). It is easy to count cases in court, but counting the cases that have not been filed proves more problematic. The problems include, for example, what kinds of cases should be in court, are there too many (or too few) court cases, and what populations do the courts serve? Through such inquiries, the very nature of what constitutes a 'legal' or 'justiciable' claim is called into question (Genn, 1999). Comparative and longitudinal studies of legal caseloads also fueled the interest in improving understanding of the relation between individual disputes, social conflicts, and court cases (Munger, 1990). Such concerns led scholars to focus explicitly on the social construction of disputes and their emergence in court.

Recognition that adjudication in court provided only one way to resolve conflicts, and a costly way at that, encouraged the development of alternative processes for dispute management. Interest in alternatives to courts also led to research on dispute transformation, as scholars explored the impact of different institutional mechanisms on the emergence and management of disputes. Alternative dispute resolution (ADR) provided processes such as mediation and arbitration as alternatives to adjudication in the courtroom (Goldberg et al., 1985; Tomasic and Feeley, 1982). ADR advocates praised its informality, lower cost, speed, and case outcomes particularized to the needs of the disputants (Menkel-Meadow, 1985; Goldberg et al., 1985). ADR critics voiced concerns about a two-tier legal system with courts reserved for wealthier litigants and alternatives for others, and about the lack of legal norms and public accountability for dispute management outside of court (Fiss, 1984; Harrington, 1985). Scholars on both sides of the debate sought to bolster their positions by

gathering information on how disputes are transformed through negotiation, mediation, arbitration, or adjudication.

Another interest in dispute transformation came from sociologists studying case processing in the criminal justice system. Criminal justice research showed how officials negotiated the meaning of events and the identities of suspects in processes of plea bargaining. Crimes are defined according to their normal situational and social features, as well as by legal codes (Sudnow, 1965). Psychological studies of negotiation in conflict resolution also examined dispute transformation. They focused not only on how players tried to maximize their own interests, but also on how they sought actively to define the conflict frame, that is, the cognitive interpretation of the conflict (Pinkley and Northcraft, 1994).

Finally, political scientists studied dispute transformation in order to better understand legal mobilization and the role of courts in society (McCann, 1994; Mather, 1998). Test case litigation involves the construction of individual lawsuits as vehicles for articulating and advocating collective political interests. In successful litigation, disputants may become important creators of law and lawyers are spokespersons for their cause. Court trials may be confined to the individual facts and issues in dispute, or broadened to address the normative implications and wider political meaning of the dispute. As a consequence of cause lawyering, interest group activity, or media attention, political trials may result from such dispute expansion. Parties in litigation, their lawyers, and court officials may each seek to transform disputes in different ways, for different political ends.

The Emergence and Transformation of Disputes

A hypothetical sexual harassment case can illustrate some of the central issues in the emergence and transformation of disputes. Consider a situation in which an office manager makes what could be interpreted as sexual overtures toward his secretary. He frequently tells crude jokes, embarrasses her with comments about her looks and dress, and invites her for after-hours dates. She is not attracted to him and objects to his behavior, but she likes her job. What would be her response? She might simply brush him off and try to live with the situation ('lump it'); seek advice from coworkers, neighbors, friends; leave her job and seek work elsewhere ('exit'); pursue an internal complaint within her place of work, or seek legal counsel outside the job and file a claim of sexual harassment.

This example suggests how the secretary's response to her manager depends first on recognizing and identifying a problem, which is shaped, in turn, by her own experiences, by the responses of others in her social surround, and by the availability of alternatives for managing the situation. Her handling of it may or may not lead to a legal case. For many women employees in the United States – and still for many worldwide – the occasional lecherous boss was part of a normal working environment. Cultural and political changes led to women's recognition of certain workplace experiences as grievances. Women's groups mobilized to expand federal law against sex discrimination in employment (Title VII of the Civil Rights Act) to add the newly named category for such grievances: 'sexual harassment' (MacKinnon, 1979). On occasion, supporters of an employee – such as coworkers, a women's group, or employees' union – might broaden the scope of the conflict to transform her individual problem with the offending manager into a larger claim against sexist working conditions throughout the office. Additional issues such as gender discrepancies in pay and working conditions or racial harassment might be added to this emerging dispute. Advice from a civil rights lawyer could lead to a class action lawsuit, which would further broaden the scope of the conflict and add new parties to the case. Alternatively, internal processes of conflict management within the organization could depoliticize the matter, remove any aspect of sex discrimination or sexual harassment, and narrow it into a personality conflict between the two parties, thus transforming an issue of public law into a private dispute (Edelman et al., 1993). In short, both the meaning and the course of a conflict are contingent. They depend on the perceptions, actions, and experiences of various parties, and on the potentials for response provided by language, institutions, and support networks of various kinds. Furthermore, the ways in which a problem is defined – and whether it is even seen as a dispute or not – reinforces certain power relations and ideas, and links law to everyday life.

The Disputing Pyramid: Naming, Blaming, Claiming

Why are some injuries or problems ignored, while others become disputes? And why do some forms of trouble end up as court cases but most do not? These questions inspired a number of influential studies in the 1970s and 1980s that described a 'disputing pyramid,' or 'legal iceberg' (Galanter, 1974; Miller and Sarat, 1981) with vast numbers of events that might become grievances at the bottom, fewer events that have 'matured' into grievances in the middle, still fewer legal claims toward the top, and only a small number of actual cases in court (Galanter, 1974; Miller and Sarat, 1981). In the pyramid or developmental approach to disputing, the emergence of disputes depends first on an individual's perceiving an injury or problem ('naming'), then attributing the problem to the fault of another ('blaming'), and finally confronting the opposing party and seeking some kind of remedy ('claiming') (Felstiner et al., 1981). Many injuries are never perceived as such, and still others are not acknowledged because of cultural disposition, institutional barriers, or the lack of social support. Scholars adopting this approach have been concerned with the progress of 'perceived injurious experiences' through the pyramid, and specifically with how differences in the class, education, work situation, and social networks of an injured party might affect the process of transformation, leading to 'grievance apathy' (the failure of a grievance to 'mature' into a dispute) or the escalation of grievances into claims, including legal claims (Felstiner et al., 1981).

Early thinking about these issues suggested that movement of grievances to the top of the disputing pyramid depended on demographic characteristics of the parties (e.g., class, education), the relationship between the parties, the type of claim, and the relation that the parties have to the legal system. Further research showed individual demographics not to be

very significant; instead, the type of claim (e.g., family, consumer, discrimination) overwhelmingly determines the shape of the disputing pyramid, even across different countries (Kritzer, 2011). Murayama (2012: 77), for example, compares rates of grievances, claims, and disputes in Japan and the United States and concludes: "nationality does not determine dispute behavior – problem type does." Institutionalized procedures and remedies for handling certain kinds of conflicts may encourage claiming by lowering costs and making the disputing process more accessible and predictable. In addition to social and institutional factors, psychological factors also affect disputing. Individuals vary in their claims consciousness and in their propensity to assert claims or pursue legal rights. This variation is associated with preferences for different modes of conflict resolution, different understandings of the legal system, and with self-described personality attributes, but appears to be independent of demographic status (Vidmar and Schuller, 1987; Ewick and Silbey, 1998).

Transformation of Disputes: The Dialectic of Narrowing and Expansion

Studies of the series of transformations through which an (unperceived) injury becomes a legal case in court provided an important contribution to the sociological study of law by placing the 'grievant' or disputant individual at the center of the disputing process (Felstiner et al., 1981). At the same time, focus on the individual as the primary agent of transformation, and on action as a sequence of choices ('lumping,' 'blaming,' 'claiming,' 'disputing') at key points on a 'decision tree,' conceptualizes transformation as dyadic, linear, intentional, active, and focused on a series of stages through which each 'perceived injurious experience' passes as it 'matures' into a dispute. But many such experiences, and the disputes that emerge from them, evidence a more complex transformational dynamic, one that "takes place nonconsciously and is not the product of reasoned analysis or deliberate choice" (Engel, 2013: 304).

An alternative approach to disputing conceptualizes the emergence of disputes not as a linear process, but as one characterized by a 'dialectic' of narrowing and expansion (Santos, 1977); 'choice' is embodied in a system of dispositions (Bourdieu, 1977) that shape, and are in turn shaped by, the process of disputing; and the focus is as much on third-party transactions – collaborative, contentious – as on individual agency. Dispute transformation thus becomes a key mechanism in the production of social life, and time is put at the center of a process that is characterized by recursion, narrative reformulation, third-party interaction, and the ongoing reconfiguration of legal identities (Mather and Yngvesson, 1981; Yngvesson and Coutin, 2006; Engel, 2013). Indeed, as Coutin (2011: 570) argues, "law's complex temporal character" takes shape as part of this process of transaction and transformation, and in this sense, the documents and texts of which law is composed might themselves be considered agents of transformation, in that they contain "the residue of prior negotiations and transformations, a residue that leads forward as well as into the past" (2011: 572). The capacity of law to 'return' to the past or project into the future limits the agency of the actors who use it, even as they may exploit law's indeterminacy and openness to (re)interpretation.

The following sections explore three different aspects of the dialectic of narrowing and expansion in the transformation of disputes: framing and the role of language; the role of lawyers, courts, and other institutions in transformation; and the relation of dispute transformation to the articulation, imposition, circumvention, and creation of legal and other normative frameworks.

Framing: Language and Dispute Transformation

The definition of a dispute articulated by participants is not neutral. It orders 'facts' and invokes 'norms' in ways that reflect the interests and dispositions of the parties, or that anticipate the reactions of others (Mather and Yngvesson, 1981). By representing parties, events, and claims in particular ways, or by including or excluding certain facts, disputants construct an account of what transpired that is tied to an implicit or explicit normative framework. For example, in describing an experience as 'sexual harassment,' the word '*harassment*' itself invokes a different normative meaning than, say, '*flirting*' or '*being friendly*.' Struggles over language involve negotiation over which framework to apply and which narrative to construct, and such negotiations are integral to the disputing process and its outcome (Conley and O'Barr, 1997).

Research by Marshall on the everyday construction of sexual harassment in the workplace (2003) illustrates these struggles over meaning. Marshall examined the experiences of women in administrative and clerical positions at a large university as they confronted a variety of harassing behaviors, including sexual advances and invitations, sexual banter and joking, and displays of graphic sexual materials. Three key frames emerged: an 'injustice frame' articulated by the women's movement that emphasizes the relationship of sexual harassment to discrimination and inequality; 'management frames' that distance sexual harassment from broader structures of inequality in the workplace; and 'freedom of sexual expression' frames used by women who regarded sexual interactions in the workplace as a way to exercise power in that setting (2003: 673–679).

Marshall examines the complex dynamics that came into play as women struggled to interpret the sexual behaviors of their workplace colleagues, noting that they "rarely chose a single frame for understanding … unwanted sexual attention," but tried instead to balance competing interpretations. In this delicate balancing act, "the injustice frames that characterized such experiences as discrimination" were in tension with perspectives "suggesting that they should not take it so seriously …. Thus, some women could not decide whether they had even been injured" (2003: 679). In one case, Marshall notes that a woman reframed behavior that she had initially considered to be inappropriate but unavoidable sexual conduct as 'sexual harassment,' following the circulation of sexual harassment policy information by her employer. For this woman and others like her, law became 'a tool after the fact,' with which they could 'go back and reinterpret their experiences' (2003: 684; and see Coutin, 2011). For other women, in contrast, their exposure to human-resource frames, which portrays sexual harassment 'as a personality conflict or

a management problem,' becomes a ground for adapting to behavior they find offensive and rejecting the label of sexual harassment (2003: 685).

In conclusion, Marshall suggests that sexual harassment law may contribute to normative change when it overlaps with injustice frames articulated by the women's movement, since these translate previously acceptable social behaviors into injuries, which may then become legally cognizable. At the same time, she notes that "law can inhibit social change," since legal remedies tend to "deemphasize collective solutions and instead encourage women to pursue more individualistic strategies, such as confronting harassers, lodging complaints with employers, or filing lawsuits when other options fail" (2003: 686).

The risk for privatizing what might otherwise be framed as a collective (structural) problem of sexual misconduct has also been played out on university and college campuses over the past several years, as students who complained about sexual violence have been referred to university disciplinary panels, which all too often act in the interests of the university to avoid undesirable publicity, dismissing the complaints by implicitly reframing them as part of a 'culture of drunken hook-ups' among students (Perez-Peña and Taylor, 2014: 25). The experience of a female undergraduate at Columbia University, whose complaint of being raped by a fellow student was dismissed by the internal panel, but then taken up, with a number of related cases, by a student magazine at Columbia, illustrates the dialectic of narrowing and expansion in such cases and the collaborative forms of agency that may come into play. By bringing the perspectives of the women involved into public view and suggesting that sexual violence by male students was being swept under the rug by the university, the magazine article led to rapid escalation of the conflict. It became the focus of heated debates in dorm rooms, dining halls, and social media, generating widespread student protests in support of the women and demands for change in university policy. One of the women involved further escalated the conflict by agreeing to identify herself in a front-page interview in the 4 May 2014 edition of *The New York Times*, which also documented protests by student activists calling themselves 'No Red Tape.' The activists tried to gain entrance to an event for prospective freshmen at Columbia, with red tape over their mouths, so that they could hand out letters encouraging the students to press university officials for details about resources available to victims of sexual assault (Perez-Peña and Taylor, 2014: 25).

In these cases, as in the research carried out by Marshall, the availability of 'injustice frames' for interpreting the students' experiences was crucial to their reformulation. Through the intervention of the student magazine at Columbia, the complaints were taken up by a nationwide network of student activists who made "shrewd use of the law and the media" (Perez-Peña and Taylor, 2014: 1) to recast them as violations of federal rules under Title IX of the Education Amendments of 1972. As a result, 23 students at Columbia filed complaints against the university, charging it with the mishandling of sexual misconduct cases.

The Supreme Court ruling on 26 July 2013 in *United States v. Windsor* that a ban on federal benefits for gay couples, enacted under the Defense of Marriage Act (DOMA), was unconstitutional, provides another example of the complexity of third-party interactions over framing. In this complaint, Edie Windsor successfully challenged the constitutionality of the DOMA before the U.S. Supreme Court, with a dispute about her entitlement to federal tax relief following the death of her partner of more than 40 years, Thea Spyer. Although the two had been legally married in Canada, and Windsor was Spyer's sole heir, Windsor was ineligible for the exemption on estate taxes that applies to husbands and wives, because DOMA, which was signed into law in 1996, recognized only heterosexual marriages in determining federal benefits and protections. This rendered the considerable estate Windsor inherited from her partner taxable as though they were strangers. At one level, then, this was a dispute about the recovery of Windsor's money. At the same time, it presented an opportunity for activists in the gay and lesbian community to contest the constitutionality of DOMA's differential treatment of heterosexual and homosexual marriages.

Whether Edie Windsor's complaint over a tax exemption was the right opportunity for this challenge was itself a disputed matter between her own lawyer and activists and organizations associated with civil rights litigation, such as the American Civil Liberties Union, Lambda Legal, and the Gay & Lesbian Advocates & Defenders. Activists were concerned about the fact that Windsor's complaint would present the Court "with the opportunity for a narrow ruling that would restore Windsor's money but overlook the broader question of gay marriage" (Levy, 2013: 62). But for Windsor's lawyer, a significant consideration in opting for Edie Windsor as the perfect plaintiff for a challenge to heterosexual marriage was that she did not 'look gay,' in part because she was a widow, but also due to the fact that she could be perceived as having 'aged out of carnality' (2013: 61). Eventually, in spite of lingering concerns about whether 'the story of an estate tax bill' was the right venue for challenging DOMA, as one activist interviewed said, "we decided that the smartest, most strategic thing to do was work together" (Levy, 2013: 62).

United States v. Windsor illustrates the ways in which the transformation of a dispute about money into a challenge of the normative status of heterosexual marriage is made possible by the collaborative agency of third parties with a highly specialized knowledge of civil rights law and political acumen. Likewise, the framing of sexual conduct complaints as sexual violence by student activists at Columbia was made possible by the students' 'savvy' use of social media to mobilize local and national audiences, their position at an elite institution, and the targeting of sexual violence on campus as a focus of the Obama administration (Pérez-Peña and Taylor, 2014). At the same time, the social identities of the complainants (Columbia university students and Edie Windsor, an 83-year-old widow) contributed to the successful reframing of the cases. Political groups planning test case litigation (such as *United States v. Windsor*) are well aware of the importance of having a sympathetic plaintiff to represent their cause and thus, for example, legal challenges to affirmative action in the United States have usually had white women as plaintiffs rather than men.

Reframing is fundamental to dispute transformation in a range of settings, from appeals brought to the Supreme Court to complaints about neighborhood violence heard by district court clerks in Massachusetts (Yngvesson, 1988; Merry, 1990).

In district court cases, as in the management of student sexual conduct by college disciplinary panels, or the narrowing of sexual harassment complaints in the logic of a 'management frame' as reported by Marshall, the clerk's goal is to keep the complaints out of court, by rephrasing what complainants regard as 'vicious' behavior, into normal trouble in a chaotic environment. In this way, the court distributes responsibility for what it considers 'garbage cases' – cases that are trouble for the court, or as in the sexual conduct cases discussed above, trouble for management at the university – between the disputants, while preventing an escalation of the conflict. Hearings before the clerk of court illustrate the narrowing of complaints in cases with the potential to challenge normative order in the community at large, but where complainants lack the social and economic resources to mobilize a wider audience in support of their cause.

The Role of Lawyers, Courts, and Other Institutions in Dispute Transformation

As gatekeepers to courts in many countries, lawyers act as intermediaries between disputants and the legal system. In deciding whether to represent a claimant and if so, how to frame the case, lawyers are central to the process of dispute construction. The screening practices of Chinese lawyers, for example, reflect financial, cultural, and institutional constraints on them, resulting in very little representation of workers with labor disputes (Michelson, 2006). In considering whether to use litigation against the tobacco industry to pursue the claims of sick smokers in the United Kingdom (as was done by lawyers in hundreds of cases in the United States), English lawyers (except for one firm) rejected the cases (Mather, 2009). Thus, some kinds of disputes (or the complaints of certain individuals) go forward as legal cases and others do not, due to the actions of lawyers.

Once clients have legal representation, what role do their lawyers play? Cain's (1979) classic study of English solicitors showed how often they rephrased the objectives of their clients. More recently, an important debate in the United States has centered on the extent to which lawyers escalate conflict, urging their clients to pursue formal legal strategies for problems that might be more appropriately handled informally, or dampen conflict, encouraging negotiation and out-of-court settlements. This debate has been especially contested in the field of tort law with significant attention paid to the economic incentives and disincentives for lawyers of different case strategies, and to the media portrayal of plaintiff and defense lawyers (Haltom and McCann, 2004). Similarly, in divorce, an impetus for the introduction of mandatory mediation in the 1980s was a belief that lawyers aggravated the hostility and conflict between spouses. But in fact, for most divorces in the United States, only one spouse can afford a lawyer and the other is *pro se* or else both parties are unrepresented by counsel. Even in two-lawyer divorces, attorneys typically seek to cool out their clients in order to protect the children and to preserve the long-term relationship between ex-spouses, or because lawyers see cooperative settlement to be more cost-effective, or because the law encourages equitable division of property and shared parenting (Mather et al., 2001). Considerable research in the United States and elsewhere has corroborated Sarat and Felstiner's (1995) finding that most divorce lawyers try to focus narrowly on the legal and financial issues, to the exclusion of emotional, personal, or moral issues that their clients may want to discuss.

This point underscores the more general question: To what extent are clients' stories and objectives 'heard' by counsel? One thing that lawyers clearly do is translate clients' problems into legal language. Lawyers rephrase auto accidents (or, as in the case below, torture) into torts, domestic violence into assaults, and racist actions into civil rights violations. In lawyers' offices, clients may want to pour out stories with their full social and personal context. But details that clients see as highly relevant are often dismissed by counsel as not germane to the legal case and objectives that clients seek may not be attainable within the framework of the legal system. The resulting transformation of a client's dispute through the lawyer's actions can lead to a profound discontinuity between lawyers and clients. In a survey of plaintiffs in medical malpractice cases, Relis (2007) describes the 'parallel worlds of understanding' held by plaintiffs and their lawyers, concluding that despite the financial frame of compensation required by tort law, for many plaintiffs, 'it is not about the money!' Similarly, in a study of claimants to the 9/11 Victim Compensation Fund, Hadfield (2008) describes the troubling trade-off between money and the deeply held nonmonetary values and goals of victims.

The federal torture case of *Romagoza v. Garcia* (2002) illustrates the potential and the frustration in lawyer–client collaboration while constructing a legal narrative, in a case where narrowing the dispute at one stage contributed to its eventual expansion several years later. Rubin's (2008) analysis of dispute transformation in *Romagoza* also illuminates lawyers' skill in adapting a body of law originally developed for one purpose (imprisoning or executing those responsible for crimes against a nation or against humanity), for use in tort litigation where individuals seek monetary reparations for personal injuries from former state officials. In this way, the case provides a powerful example of what Coutin (2011: 570) describes as "law's archaeology," in reference to the process through which legal artifacts produced in one forum may reshape claims brought in another, thus constituting law itself as a historical actor in the dispute transformation process.

Romagoza v. Garcia was brought before a jury in the U.S. Southern District of Florida by Neris Gonzalez and two other Salvadoran citizens, against the former Salvadoran Minister of Defense and the former head of the Salvadoran National Guard, for their role in instigating and authorizing torture by the Salvadoran National Guard. Gonzalez, who had been severely tortured when she was 8 months pregnant, was persuaded to join the lawsuit by the legal director of the San Francisco-based Center for Justice and Accountability, which wanted to initiate a lawsuit under the 1789 Alien Tort Claims Act and the 1992 Torture Victims Protection Act against ex-military officials from El Salvador, some of whom were residing legally in the United States. Gonzalez agreed to join the lawsuit as a continuation of her political struggle of 30 years against the Salvadoran state and after her unsatisfactory experience before a Truth Commission set up in 1993 by the United Nations, in which no one was held to account.

Recognizing the importance of the details of her torture to Gonzalez's goals in joining the civil lawsuit against the generals, her lawyers tried to incorporate as much of her experience into the legal narrative as possible. Nevertheless, the scope of her testimony was bounded by the procedural rules of a tort lawsuit and also needed to be tailored to an audience of U.S. citizens (the jury) with no prior knowledge of the Salvadoran Civil War. As an abstract legal category, 'torture' had to be made quantifiable and understandable for the jury, rendered as a 'scale of terror' and ultimately assigned a monetary value (Rubin, 2008: 273, 276). As a result, the most traumatic dimension of her own torture, the killing of her unborn child, had to be left out of the legal narrative. Gonzalez described this process of abstraction, quantification, and legalization as 'very technical,' adding that "emotion is not technical. Pain is not technical …. So we had to choose the most important parts of the pain in the trial, so that the courtroom could function" (Rubin, 2008: 278).

Although *Romagoza v. Garcia* was successful in that the two generals were held responsible for the torture of the three plaintiffs and were ordered to pay $54.6 million in damages, Gonzalez's larger political goals were unfulfilled by the trial. She did, however, remain hopeful that the trial would encourage others, and that "future legal actions will complete the process of justice that *Romagoza* began" (Rubin, 2008: 279). Just over a decade later, this hope was realized in two separate rulings in a Miami immigration court (April 2013; February 2014) that cited *Romagoza* to justify deportation orders against General Garcia and his codefendant in that case. Thus, this jury trial continues to leave traces, and provides a powerful example of what Santos (1977) describes as the dialectic of narrowing and expansion. In what was described as "an unusually expansive and scalding 66-page decision," the federal judge in the 2014 ruling harshly condemned General Garcia (Preston, 2014: A11). Through their use of *Romagoza* and other precedents to justify the deportation orders of the two generals, the Immigration Court rulings demonstrated how narrowing in one phase of a dispute may contribute to subsequent expansion of the same dispute many years later, in this way challenging the normative order that allowed the torture of Neris Gonzalez and other Salvadorans. The deportation orders are under appeal by the generals' lawyers (as of June 2014).

As *Romagoza v. García* suggests, institutional structures influence disputing by channeling the ways in which conflicts can be transformed. Courts, for example, often have strict rules of evidence that limit what kinds of information may be included in the construction of a case during trial. But informal negotiations outside of court, such as plea bargaining or settlement talks, have few such limits. When, for example, informal plea negotiations over disposition of a first-time drug defendant include discussions of the defendant's social background, family situation, and employment, lawyers may lean toward lenient treatment. But none of this material might be admitted in adjudication, and the resulting sentence could be much harsher after conviction at trial. Different institutional procedures transform cases in different ways, producing variation in case outcomes.

Richland's (2008) linguistic analysis of interactions between litigants and judges in a Hopi tribal court provides an illustration of this kind of variation in institutional procedure. Richland focuses on the tensions between Anglo-American legal procedure and Hopi legal heritage in a setting where tribal members were calling for a radical reclamation of legal institutions that were originally used to dominate them. He provides a detailed analysis of how Hopi judges negotiate this tension, creating 'meaningful spaces' (2008) that momentarily destabilize the truth-making practices of Anglo law by permitting the inclusion of personal histories of suffering that are open-ended and challenge the rules of evidence allowed in Anglo courts. In this way, Richland suggests, what might appear to be irreconcilable differences across practices are accommodated in ways that transform both Anglo-American law and Hopi tradition.

Attention to dispute transformation may also help to bridge presumed differences between procedures that are conventionally categorized as 'adjudication' or 'mediation.' In theory, a distinguishing feature of mediation – in contrast to adjudication – is the ability of mediators to range widely over different issues in a conflict. Whereas judges are supposed to narrow their focus to particular legal elements of a case, mediators (not bound by law) may encourage the emergence of new issues in their effort to formulate an agreement that is acceptable to both parties. Divorce mediators sometimes comment on the 'strange-looking agreements' that result from such wide-open sessions. Nevertheless, mediators may have more commonalities with judges than with other mediators in terms of how they actually handle cases, and negotiation is frequently intertwined with adjudication. Instead of assuming differences across processes, one might focus instead on how different processes influence dispute transformation – for example, through specialized or general language, through closed or open dispute hearings, or through linkages between dispute processes and other organizations in society (Yngvesson and Mather, 1983).

Dispute Transformation, the Articulation of Normative Order, and the Production of Law

The dispute transformation perspective (like other studies of dispute processing) has been faulted for its overemphasis on process to the exclusion of dispute outcome, a failure to examine the political significance of disputing, its individualistic focus, the methodological difficulty of identifying or measuring transformations, and its insufficient concern for institutions. By addressing these issues, however, researchers have redefined their work to include data that allow a more nuanced picture of the political aspects of disputing, focus attention on framing and language, and link routine disputing processes to broader questions of power, order, and law. Dispute transformation through the dialectic of narrowing and expansion thus bridges considerations of individual agency and social structure. When a secretary pursues a harassment claim against her supervisor, she is pursuing her individual dispute but at the same time her case is challenging the structure of gender relations in the local workplace. By providing the language of law and certain institutions for handling disputes, the broader political structure makes resources available to change local practices. Those legal and ideological resources, however, may be resisted by others

(e.g., through internal organizational processes) in ways that sustain existing power relationships. Most disputes are narrowed or rephrased in established categories of discourse. But, on occasion, new meanings are given to disputes – such as that described above in *Romagoza v. Garcia* (2002) and the subsequent rulings by a Florida Immigration Court (2014), or to the new meaning of marriage established by the *United States v. Windsor* (2013) litigation.

The relation between dispute transformation and political order has also been documented in studies of litigation in ancient Athens. The rhetoric and procedures of litigation, there were used to transform broad conflicts into two-party disputes, impose specialized roles and identities, create new political resources, and foreclose other options – thus, as Johnstone (1999) shows, promoting Athenian democracy. In sum, viewing how disputes emerge and transform contributes to understand both the micropolitics of dispute management and the macropolitics of disputing in society. The transformation perspective is useful cross-culturally, and across different historical periods, and helps to explain how law is created, maintained, and sometimes challenged or transformed.

Abstract

Distance education or distance learning refers to the practice of delivering education and instruction to students not physically present but interacting with the instructor and the educational process remotely (usually by computers and the Internet these days.) Although often thought to be new development dependent on modern information processing technology, the idea of distance education is possibly centuries old. This article reviews the history, definition, current configuration, and effects of distance education.

History of Distance Education

Distance education has a long history possibly even dating back more than 285 years as evidenced in a *Boston Gazette* (published in the United States) advertisement by shorthand teacher Caleb Phillips. In the advertisement, he solicited "Persons in the Country desirous to Learn this Art, may by having the several Lessons sent weekly to them, be as perfectly instructed as those that live in Boston" (Battenberg, 1721 as cited in Holmberg, 1995: Paragraph 6). Years later in 1840, Sir Isaac Pitman, an English educator who invented shorthand, began mailing texts written in shorthand to students, which they would transcribe and mail back to him for correction (Schlosser and Simonson, 2009). These examples represent the first of the three documented phases of distance education, which are: (1) correspondence study (e.g., delivered via mail), (2) higher education institutions and analog mass media (e.g., delivered via television and cable), and (3) proliferation of distance education into most educational arenas via digital technologies, delivered primarily via the Internet (Simonson et al., 2011).

Over the years, definitions of distance education have changed, most frequently reflecting the transmission medium via which educational content was delivered to learners. In some cases, as Barbour et al. (2012) found in their K-12 Survey involving several countries, "there is wide interpretation of what online learning means, and what it looks like" (p. 7). However, it can be defined by several distinguishing characteristics. To understand these characteristics, it is important to examine the 'who,' 'what,' 'where,' 'when,' and 'how' of distance education, while also recognizing that, as Larreamendy-Joerns and Leinhardt (2006) contend about online education, "there are social, political, economic, and ethical assumptions and implications in what appear to be simple actions of design and instruction" (Larreamendy-Joerns and Leinhardt, 2006: p. 567) associated with these terms. It is important to note that the terms 'distance education,' 'online education,' 'e-learning,' and 'virtual education' are often used interchangeably to mean the same thing.

Therefore, it seems logical that the definition and its meaning will likely evolve over time.

Who Participates in Distance Education?

Logically, distance education involves both instructors and students; however, a defining characteristic is that traditional institutions (such as institutions of higher education), nontraditional institutions (e.g., businesses, corporations), organizations/societies (e.g., International Society for Performance Improvement) (Schlosser and Simonson, 2009), and governments offer distance education. More recently, with the emergence of massive open online courses (MOOCs), other organizations have become involved in distance education offerings, although the majority of those who participate in distance education affiliate in some way with higher education institutions. Additionally, distance education, often referred to as 'virtual schooling,' has been growing in P-12 schools, although most distance education at this educational level involves blended learning (Barbour et al., 2012).

The US Department of Education's National Center for Education Statistics (NCES), several researchers (e.g., Allen and Seaman, 2008, 2010, 2011, 2013, 2014) and organizations (e.g., International Association for K-12 Online Learning) have tracked participation in distance education in institutions of higher education and in public K-12 schools. Surveys of distance education participation in the United States illustrate that although it has grown exponentially over the past decade, the unfettered growth has slowed down. For example, according to Allen and Seaman (2014), "the online enrollment growth rate of 6.1 percent is the lowest recorded in this report series" in institutions of higher education (p. 4).

What Is Distance Education?

In the twenty-first century, distance education involves students learning in a location(s) other than where the instructor is via digital technologies, synchronously and/or asynchronously. Allen and Seaman (2013) provide several different types of distance education courses, as **Table 1** outlines.

Distance education can be equated by the 'Online' category in **Table 1**; however, others may contend that even 'blended/hybrid' courses are a form of distance education, too.

Table 1 Prototypical course classifications for online learning

Proportion of content delivered online (%)	*Type of course*	*Typical description*
0	Traditional	Course where no online technology used – content is delivered in writing or orally.
1–29	Web facilitated	Course that uses web-based technology to facilitate what is essentially a face-to-face (F2F) course. May use a course management system (CMS) or web pages to post the syllabus and assignments.
30–79	Blended/hybrid	Course that blends online and F2F delivery. Substantial proportion of the course is delivered online, typically uses online discussions, and typically has a reduced number of F2F meetings.
80–100	Online	A course where most or all of the content is delivered online. Typically have no face-to-face meetings.

Allen, I.E., Seaman, J., 2013. Changing the Course: Ten Years of Tracking Online Education in the United States. Babson Survey Research Group and Quahog Research Group, p. 7.

Where Does Distance Education Occur?

Another unique characteristic of distance education is its 'location.' Historically, distance education involved some kind of 'geographic separation' (Simonson, 2009; as cited in Simonson et al., 2011: p. 126) between the instructor and his/her students and students themselves. However, with the advent of the Internet, it is possible for there to be little or even no geographic separation between the instructor and students and/or between students because two individuals can participate in distance education sitting right next to each other in the same location, but on two different computers. Twenty-first century distance education happens anywhere – anywhere an individual can access the course/distance education experience materials – which is usually online (via a computer connected to the Internet). Moreover, in distance education an instructor may incorporate some face-to-face (F2F) instruction along with distance education. This 'blending' of distance and F2F instruction is often referred to as blended or hybrid education or learning.

When Does Distance Education Occur?

Distance education consists of instruction that occurs synchronously, asynchronously, or both synchronously and asynchronously. Synchronous courses require the learners and instructor(s) to 'meet' online at the same time for exchanges of information via audio or web conferences, screencasts, online chats, interactive whiteboards, sharing of applications, instant messaging, and even texting. Asynchronous interactions can occur using all of these methods, in addition to others such as discussion boards, blogs, wikis, and many other tools. A differentiating characteristic is that learners are not required to meet 'live' with their instructor or peers. Moreover, it is feasible for the learning materials to be disseminated 24/7 via the Internet and across any time zone in the world – the distance education classroom is always 'open' with materials available to students any time of the day, anywhere, as long as there are no restrictions on accessing materials.

How Does Distance Education Occur?

Two defining aspects of how distance education occurs involve technology and interaction. Often there is overlap between these two because technology fosters student-to-student, student-to-content, and student-to-instructor interaction. Technology is critical because it is through technology that instructors and students can access, engage, and participate in distance education. Moreover, various technologies can serve as both the medium (e.g., Internet-based course available in a course management system) and/or mechanism or tool (e.g., use of screencasting software to develop screencasts) for developing distance education. For example, a course management system or learning management system may be utilized by an instructor to house and deliver the instruction to students. They might also use web conferencing tools embedded within this system or an outside vendor to offer synchronous sessions with students and/or record a presentation explaining content.

Interaction, "commonly understood as actions among individuals" (Abrami et al., 2011: p. 86), is another important characteristic of distance education because students learn through student–student, student–instructor, and student–content interaction (Abrami et al., 2011; Bernard et al., 2009; Moore, 1989). Bernard et al. (2009) found that interaction positively affects student learning. However, they caution that instructors should not focus on increasing the quantity of interactions, but rather focus on increasing the quality of interactions.

Why Does Distance Education Occur?

There are many reasons why institutions, organizations, instructors, and students participate in distance education. These may range from the potential to reduce costs (e.g., learners do not need to travel to one location to learn – note that some argue quality distance education requires an investment, so the reduction in cost may not be realized for several years), the ability to increase flexibility of when learners learn (e.g., students can determine their own learning schedules – they do not have to learn only on the instructor's schedule), the potential to involve expert instructors from a variety of locations (i.e., instructors do not have to be from one's institution/organization nor do they have to be physically present), and the possibility to make education accessible to those who cannot participate (e.g., because they cannot move to the institution).

Distance Education in Higher Education

Distance education in higher education institutions started in the nineteenth century. One of the first documented instances was the University of Chicago's correspondence courses offered by William Rainey Harper in 1883 (Distance Learning, n.d.). Since then, distance education in higher education institutions has evolved and as noted previously, can be categorized by three major periods. However, Larreamendy-Joerns and Leinhardt (2006) view distance education through three different historical lenses – via the promise of democratization, the tension between professional education and liberal arts education, and the issue of instructional quality. Their work provides a different lens for understanding distance education.

Massive Open Online Courses (MOOCs)

MOOCs are non-credit-bearing courses typically offered for free by numerous universities and organizations to anyone interested in enrolling in these courses. Distinct features of MOOCs are that they are designed for 'massive' participation – thousands, even hundreds of thousands can participate in a MOOC – and students do not need to be enrolled in or even affiliated with the sponsoring organization offering the MOOC to register. Some MOOCs offer certificates upon successful course completion for a fee, whereas others do not. Often MOOCs are taught in F2F settings as credit-bearing courses at an institution with students enrolled in degree programs. The F2F lectures are then recorded and disseminated online to the MOOC students. These lectures typically involve a professor offering a weekly lecture, offered for a varying number of weeks depending on the course, accompanied by a multimedia presentation with visuals and questioning from students in the audience (the F2F, paying students). The lectures are recorded and made available by a MOOC provider. Therefore, in a MOOC, it is not unusual to find students who have paid to take a course for credit and in a degree program studying parallel (with no interaction at all) or alongside (with some interaction, for instance in online discussions) students enrolled for free. However, many MOOCs are designed only as a MOOC and not also as a F2F course. Currently there are no standards as to how MOOCs are offered – it is unclear if there ever will be.

Who Is Offering MOOCs?

MOOCs are being offered by organizations such as Coursera (https://www.coursera.org/), edX (https://www.edx.org/), 2u (http://2u.com/), and Udacity (http://www.udacity.com/). These organizations consist of consortia of different universities who support the provider in some way. However, in the future, it will not be surprising if corporate and government organizations consider offering their own MOOCs, too, for many of the same reasons universities are exploring the possibilities of MOOCs.

Interest and enrollments in MOOCs are quite high (e.g., over 100 000 students enrolled in a MOOC offered at Stanford University) and will likely grow; however, persistence in MOOCs shows that it is quite low (Rosen, 2012), with small percentages of the nonpaying students actually completing courses. It is too soon to tell why and whether or not this will continue to be the case with MOOCs.

Distance Education in P-12 Schools

The iNACOL is one of the most active advocates for distance education in P-12 schools. Its mission is "to ensure all students have access to a world-class, education and quality blended and online learning opportunities that prepare them for a lifetime of success" (iNACOL, 2013: p. 1). As a result of its mission, iNACOL has sponsored numerous reports on distance learning in P-12 settings. For instance, in 2011, it sponsored a survey of several countries around the world to gain a better understanding of distance education in P-12 schools (see Barbour et al., 2012). The researchers found four trends:

1. Blended and online choices are most available to students in urban areas from developed countries (p. 10).
2. Growth in digital learning stems from shared authority between local schools and national governments (p. 10).
3. Specialized teacher training is not required, but is encouraged and available (p. 12).
4. Blended learning is occurring with much greater frequency than online learning (p. 13).

In the United States, distance education in P-12 schools is growing as iNACOL (2013) has found. For example, during the 2013-2014 academic year, "25 states had state virtual schools operating … and 29 states and Washington, DC had statewide full-time online schools operating" (p. 1). Additionally, several states such as Michigan, Florida, and Virginia require high school students to complete one online course to graduate (Sheehy, 2012).

Abstract

This article describes a set of situations in which a random variable with a complicated probability distribution can be approximated well by another, better understood and studied probability distribution. The first example is the normal distribution which approximates the distribution of many random variables arising in nature. This approximation is based on the central limit theorem. Generalizations of this theorem provide a second set of approximations called the stable laws. A third example arises when one is considering extremes, or the maximum of a set of random variables. Here, the family of extreme value distributions is shown to provide accurate approximations. Moreover, the excesses over a high level can be approximated by a generalized Pareto distribution. The final example involves the distribution of the times between events, such as system failures. Under certain conditions, these times can be approximated well by an exponential distribution.

Every random variable has its own particular distribution. It is, however, very useful if one can use a well-studied distribution as an approximation. This article describes a set of situations in which a random variable with a complicated probability distribution can be approximated well by another, better understood and the studied probability distribution. The first example is the normal distribution which approximates the distribution of many random variables arising in nature. This approximation is based on the central limit theorem. Generalizations of this theorem provide a second set of approximations called the stable laws. A third example arises when one is considering extremes, or the maximum of a set of random variables. Here, the family of extreme value distributions is shown to provide accurate approximations. Moreover, the excesses over a high level can be approximated by a generalized Pareto distribution. The final example involves the distribution of the times between events, such as system failures. Under certain conditions, these times can be well approximated by an exponential distribution. Consequently, the corresponding point process (or event history) can be approximated by a Poisson process.

Normal Approximations

The normal or Gaussian distribution has a probability density function (p.d.f.) given by

$$f(x) = \frac{1}{\sigma\sqrt{2\pi}}\exp\left(-\frac{1}{2}\left(\frac{x-\mu}{\sigma}\right)^2\right) \quad -\infty < x < +\infty$$

where the parameter μ is the mean or median and σ is the standard deviation. The standard normal distribution corresponds to the special case in which $\mu = 0$ and $\sigma = 1$, for which the p.d.f. is given by

$$f(x) = \frac{1}{\sigma\sqrt{2\pi}}\exp\left(-\frac{1}{2}x^2\right) \quad -\infty < x < +\infty$$

The normal distribution serves as an excellent approximation to many random variables that arise in nature. The reason for this lies in the central limit theorem, the simplest version of which states:

Theorem (Central Limit Theorem)

Suppose $\{X_r\}_{n=1}^{\alpha}$ is a sequence of independent identically distributed (i.i.d.) random variables with cumulative distribution function F, mean μ, and variance $\sigma^2 < \infty$. Then

$$Z_n = \frac{\sum_{i=1}^{n}(X_i - \mu)}{\sigma\sqrt{n}} \Rightarrow \Phi$$

where Φ represents the c.d.f. of a standard normal distribution and $\Rightarrow$ denotes weak convergence.

This theorem says that the standardized partial sums of the $\{X_r\}_{n=1}^{\infty}$ sequence converge weakly to a standard normal distribution.

This theorem has many generalizations which allow for the $\{X_r\}_{n=1}^{\infty}$ to have different distributions (so long as each random variable has finite variance and contributes only a small part to the sum) and to have a dependency structure (so long as the correlation among the variables diminishes rapidly enough). The reader should consult Distributions, Statistical: Special and Continuous for additional information about the normal distribution. The textbook by DeGroot (1986) offers examples of the application of the central limit theorem, some extensions of the basic theorem, and discussions of weak convergence, also known as convergence in distribution. The reader should consult the text by Billingsley (1995) for the precisely stated theorems.

The central limit theorem indicates that suitably standardized sums of independent random variables will have an approximate normal distribution. Thus, any random variable which arises as the sum of a sufficiently large number of small random components can be modeled accurately by a normal distribution. This is especially appropriate for error distributions, where the error term is the sum of a number of different sources of error. The question of how large n must be for the approximation to be accurate depends on two factors: (1) the degree of accuracy required and (2) the underlying distribution F. A common 'rule of thumb' is that the normal approximation

can be safely used when $n \geq 30$ as long as F is not highly skewed and a high degree of accuracy is not required. The normal distribution is commonly used as a model for many statistical problems especially in linear models; see Linear Hypothesis and Linear Hypothesis: Regression (Basics) for details.

Stable Distributions

In this section, we present an extension of the central limit theorem. When $\{X_r\}_{n=1}^{\infty}$ is a sequence of i.i.d. random variables, each having a finite variance, then the partial sums of these variables can be normalized to converge weakly to a normal distribution. When the underlying random variables do not have a finite variance, then normalization of the partial sums can still lead to weak convergence to a nondegenerate limiting distribution; however, the limiting distribution will no longer be normal, but will instead be a *stable* distribution.

Definition (Stable Distributions)

A distribution F is stable if given any three i.i.d. random variables, X_1, X_2, X_3, with distribution F and any constants c_1, c_2, there exists constants a and b (depending upon c_1, c_2) such that $c_1X_1 + c_2X_2$ has the same distribution as $a + bX_3$. If $a = 0$, the F is *symmetric stable*.

This means that any linear combination of two i.i.d. random variables with a common stable distribution can be transformed linearly to have the same stable distribution. This definition can be used to prove that if $\{X_r\}_{n=1}^{\infty}$ are i.i.d. with a stable distribution F, then there exist constants a_n, b_n such that $\frac{\sum_{i=1}^{n} X_i - a_n}{b_n}$ also has c.d.f. F. The symmetric stable distributions are most easily described by their characteristic functions.

Theorem (Characteristic Function of a Symmetric Stable Law)

A standard symmetric stable distribution has characteristic function $\phi(s) = e^{-|s|^{\alpha}}$ for $0 < \alpha \leq 2$. Two special cases are the normal (0, 1) distribution ($\alpha = 2$) and the standard Cauchy distribution ($\alpha = 1$). The following theorem indicates that the non-degenerate stable laws represent all possible limiting distributions for sums of i.i.d. random variables.

Theorem

Suppose $\{X_n\}_{n=1}^{\infty}$ is a sequence of i.i.d. random variables with cumulative distribution function F, and suppose that there are sequences of constants, $\{a_n\}_{n=1}^{\infty}$ and $\{b_n\}_{n=1}^{\infty}$ for which $\frac{\sum_{i=1}^{n} X_i - a_n}{b_n}$ a non-degenerate limiting c.d.f. Then G is a nondegenerate stable law.

The family of stable distributions represents a wider class of possible limits of sums of i.i.d. random variables. The distributions other than the normal have heavier tails than the normal distribution. Informally, a symmetric distribution with exponent $\alpha < 2$ has finite moments of order less than α. For example, the Cauchy distribution ($\alpha = 1$) does not have a first moment, but all moments less than 1 are finite. The stable distributions have been used to model certain economic variables and the return of financial assets such as stocks or currency exchange rates. See Distributions, Statistical: Special and Continuous for additional information on the Cauchy distribution. The reader should consult Billingsley (1995), Embrechts et al., (1997), or Lamperti (1966) for more detailed information on stable distributions and the theorems underlying this more general central limit problem.

Extreme Value Distributions

Another type of approximation occurs when one is studying the maximum of a set of random variables. This situation is particularly relevant in the casualty insurance industry, where interest centers on the largest claims. These situations also arise in engineering and environmental problems, where a structure such as a dam or building must withstand all forces, including the largest. Suppose $\{X_n\}_{n=1}^{\infty}$ is a sequence of i.i.d. random variables with common distribution function F. Suppose that x^* denotes the rightmost support point of F, the smallest x for which $F(x) = 1$, or $+\infty$ if no such x exists. We consider $\{M_n\}_{n=1}^{\infty}$ where $M_n = \max_{\{1 < i < n\}} X_i$, the largest among the first n random variables in the sequence. Fisher and Tippett (1928), a classic paper, showed that if there are sequences of constants $\{a_n\}_{n=1}^{\infty}$ and $\{b_n\}_{n=1}^{\alpha}$ for which $\frac{M_n - a_n}{b_n} \Rightarrow H$, a nondegenerate limiting c.d.f., then H takes on one of three possible forms:

1. The Gumbel distribution

$$H(x) = \exp\left(-e^{-x}\right), \quad -\infty < x < +\infty$$

This limiting form arises when $x^* = \infty$ and the underlying distribution F has a right-hand tail which decreases at an exponential rate. Specifically, if there exists a constant $b > 0$ for which $\lim_{x \to \infty} \exp(x)(1 - F(x)) \to b$, then $M_n - \log(nb)$ converges to the Gumbel distribution as $n \to \infty$.

2. The Fréchet distribution

$$H(x) = \begin{cases} \exp\left(-x^{-a}\right) & \text{if } x > 0 \\ 0 & \text{if } x \leq 0 \end{cases}$$

where $\alpha > 0$. This limiting form arises when $x^* = \infty$ and the right tail of the underlying distribution F has a tail which decays at a polynomial rate. Specifically, if $\lim_{x \to \infty} x^{\alpha}(1 - F(x)) \to b$, for some constant $b > 0$ and $\alpha > 0$, then $M_n/(bn)^{1/\alpha}$ converges to the Fréchet distribution as $n \to \infty$.

3. The Weibull distribution

$$H(x) = \begin{cases} \exp\left(-(-x)^{\alpha}\right) & \text{if } x \leq 0 \\ 1 & \text{if } x \geq 0 \end{cases}$$

where $\alpha > 0$. The above distribution is concentrated on $(-\infty, 0)$, and it is the negative of the traditional Weibull distribution. This limiting form arises when $x^* < \infty$, i.e., the underlying distribution F is bounded above by a constant. Specifically, assume $\lim_{x \to x^*} (x^* - x)^{-\alpha}(1 - F(x)) \to b$ for some constants $b > 0$ and $\alpha > 0$, then $(nb)^{1/\alpha}(M_n - x^*)$ converges to the Weibull distribution defined above as $n \to \infty$. The reader should consult Distributions, Statistical: Special and Continuous for additional information on the Weibull distribution.

Fisher and Tippett (1928) proved that these are the only possible limiting forms. It is, however, important to point out that, for some underlying F, there may be no set of constants $\{a_n\}_{n=1}^{\infty}$ and $\{b_n\}_{n=1}^{\infty}$ for which $\frac{M_n - a_n}{b_n} \Rightarrow H$. The conditions under which this convergence occurs are complicated, and the interested reader is referred to Embrechts et al., (1997). Lamperti (1966) also provides a nice treatment of extreme value theory.

The three extreme value distributions given above describe the limiting of the maximum of a random sample. There is a second random quantity that is related to the maximum and is interesting in it own right. Suppose we begin with a random variable X with c.d.f. F and consider the conditional excess distribution of X, $X-u$, given that it exceeds u. Specifically, consider $F_u(x) = p(X - u \leq \ |X > u)$. One could also consider the expected excess, conditional on the random variable exceeding u, $e(u) = E(X - u|X > u)$. This distribution and expectation arise in engineering and insurance problems, where the quantity above a certain high limit is of concern, such as the insurance claim above a large deductible amount.

The standard generalized Pareto distribution is a family of c.d.f.s indexed by a parameter $\theta \in (-\infty, +\infty)$ given by

For $\theta < 0$,

$$G_\theta(x) = \begin{cases} 0 & \text{if } x < 0 \\ 1 - (1 + \theta x)^{-1/\theta} & \text{if } 0 \leq x \leq -1/\theta \\ 1 & \text{if } x \geq -1/\theta \end{cases}$$

For $\theta = 0$,

$$G_o(x) = \begin{cases} 0 & \text{if } x < 0 \\ 1 - \mathrm{e}^{-x} & \text{if } x \geq 0 \end{cases}$$

For $\theta > 0$,

$$G_\theta(x) = \begin{cases} 0 & \text{if } x < 0 \\ 1 - (1 + \theta x)^{-1/\theta} & \text{if } x \geq 0 \end{cases}$$

The family can be enlarged by adding a location and scale parameter.

For a given value of θ, the probability distribution of F_u approaches that of a generalized Pareto distribution as $u \to x^*$. Thus, the generalized Pareto distribution can be used to approximate the probability distribution of excesses over a high limit. The mean excesses can also be modeled using a generalized Pareto distribution.

The reader should consult Embrechts et al., (1997), a comprehensive treatment of extreme value theory and for exact conditions and statements of these approximation results.

Times between Events in a Point Process

A random point process is a sequence of events (or points) that occur in time. Common examples of point processes are event histories, the failure times of systems, arrivals of customers to a service facility or the firing of neurons in the human nervous system. Clearly, modeling such point process phenomena can be very complicated and detailed. There is, however, an approximate result that is widely useful in such modeling. Specifically, for an important class of point processes, a reasonable approximation is that the times between events are i.i.d. random variables with an exponential distribution, a p.d.f. given by:

$$f(x) = \begin{cases} \lambda e^{-\lambda x} & \text{if } x \geq 0 \\ 0 & \text{if } x < 0 \end{cases}$$

with $\lambda > 0$. The parameter λ measures the rate at which the events occur and is measured in units of events per unit time. Such a point process is called a Poisson (λ) process. Poisson processes have three important properties: (1) the number of events in an interval of length L is a random variable with a Poisson (λL) distribution; (2) the number of events in non-overlapping time intervals are independent random variables; and (3) the probability of exactly one event in an interval of length h, divided by h, converges to λ as $h \to 0$. Hence events cannot occur simultaneously in a Poisson process. See Distributions, Statistical: Special and Continuous for additional information on the exponential distribution.

Now, suppose that the point process is composed of the superposition of a large number of independent point processes, each individually with insignificant intensity function. Then the superposed (aggregated) point process converges (as the number of components superposed increases) to a Poisson process. The reader should consult the text by Karlin and Taylor (1975) for a precise statement of this theorem. This situation is very realistic for system failures in which the system is composed of many different parts, the failure of any one of which leads to system failure. Each component has its own failure distribution, and the time to the next failure will be the minimum of these failure times, which will converge to an exponential distribution as the number of components increases. A similar situation occurs with aggregate customer arrival processes, where the aggregate process is the superposition of a large number of different arrival processes. As the number of different arrival sources increases, the limiting aggregate arrival process will become Poisson. The reader should consult Queues to learn about the use of the exponential distribution, and the Poisson process as a model for customer arrival processes.

Further Reading

The reader should consult a basic textbook on probability such as DeGroot (1986) for information on many of the distributions mentioned in this article, for a description of the basic central limit theorem and examples of its use, and for some more general results. Billingsley (1995) provides a more comprehensive and technically detailed treatment of the central limit theorem, the stable laws and the extreme value distributions. Finally, the book by Embrechts et al., (1997) gives a comprehensive treatment of the extreme value distributions and associated approximation theorems.

Abstract

This article introduces a set of specific probability distribution of random variables that arise frequently in modeling social science phenomena. The article focuses on the absolutely continuous case in which a probability density function can be defined. The special continuous distributions presented include the uniform, beta, normal, exponential, gamma, Weibull, Chi-square, Student *t*, *F*, and Pareto. The concept of a failure rate function is also introduced. Multivariate probability distributions are introduced, and the bivariate normal distribution is presented.

Continuous probability distributions are used widely in probability and statistics when the underlying random phenomenon is measured on a continuous scale. Common examples include the time until an event occurs, such as the failure time of a component or system, or most human physical dimensions such as height or weight. In some cases, the underlying random quantity has a discrete set of possible values. If that set is large, it may be possible to rescale those values and treat them as continuous. Continuous distributions arise frequently in the social sciences, for example in IQ or educational testing settings in which the scale is designed to yield a normal distribution of performance. Economic measurements such as income levels are often modeled using continuous distributions. Many observed distributions do not fit any of the standard distributions presented in this article (for example, they may be skewed when compared with the normal distribution); however, it may be possible to apply a transformation to the variable in question to make it fit one of the standard distributions better. In this article, we begin by describing univariate probability distributions, then specialize to the absolutely continuous case. The concept of a failure rate function as an alternative way to describe an absolutely continuous distribution is also introduced. The next section introduces special continuous distributions, including the uniform, beta, normal, exponential, gamma, Weibull, Chi-square, Student *t*, *F*, and Pareto. The entry concludes with a definition of multivariate distributions, and the bivariate normal distribution is presented.

Definitions and General Properties

A univariate random variable X has a probability distribution which is defined by its cumulative distribution function (c.d.f.),

$$F(x) = P(X \le x), \quad -\infty < x < +\infty$$

A c.d.f. has several properties:

a. $F(x)$ is non-decreasing, i.e., $F(x) \le F(y)$ if $x < y$;
b. $\lim_{x\to-\infty} = F(-\infty) = 0$;
c. $\lim_{x\to+\infty} = F(+\infty) = 1$;
d. F is right continuous, i.e. $\lim_{h\to 0} F(x+h) = F(x)$; and
e. $P(a < X \le b) = F(b) - F(a)$, $-\infty \le a < b \le +\infty$.

When the c.d.f. is a step function, $\{(x_i, p_i)\}_{i=1}^{\infty}$, with a jump of height p_i at location x_i, $1 \le i < \infty$, then the associated probability distribution is called a *discrete distribution*. If the c.d.f. is a continuous function, the associated probability distribution is called a *continuous distribution*. When the c.d.f. has jumps satisfying $0 < \sum_{i=1}^{\infty} p_i < 1$, the distribution is said to be *mixed*.

For continuous distributions, we can define the derivative, $f(x) = dF(x)/dx$. The function f is called the probability density function (p.d.f.). When the c.d.f. is absolutely continuous, then one can integrate the p.d.f. to recover the c.d.f., that is,

$$f(x) = \int_{-\infty}^{x} f(u)du, \quad -\infty < x < \infty$$

One can calculate the probability of an event by integrating the density function; for example, if the event is an interval $[a, b]$, then

$$f(x < X < b) = \int_{a}^{b} f(x)dx$$

If X has a continuous probability distribution, then $P(X = x) = 0$ for any value $-\infty < x < +\infty$. The interpretation of the p.d.f. is that $P(x \le X \le x + h) \approx f(x)h$ for small $h > 0$. That is, the probability a random variable with an absolutely continuous probability distribution takes a value in a small interval of length h is given by the probability density times the length of the interval.

For absolutely continuous distributions, the c.d.f. F and the p.d.f. f are equivalent in that one can be derived from the other. An absolutely continuous probability distribution might also be described by its failure rate function, also known as the hazard function. This function is often denoted by $\lambda(x)$ and is defined by:

$$\lambda(x) = \frac{f(x)}{1 - F(x)}$$

The failure rate function arises naturally in specifying the reliability of a system or in mortality tables. This function gives the probability that a system will fail (person will die) in the next small interval of time conditional on it not yet having failed (died) up to the present time. The failure rate function satisfies

$$p(X \le x + h | X \ge x) \approx \lambda(x)h$$

The c.d.f., $F(x)$, can be derived from $\lambda(x)$ from the formula

$$F(x) = 1 - \exp\left(-\int_{-\infty}^{x} \lambda(u)\mathrm{d}u\right)$$

where $\lambda(x)$ can be any function satisfying $\lambda(x) \geq 0, \int_{-\infty}^{x} \lambda(u)\mathrm{d}u < \infty, -\infty < x < \infty$ and $\int_{-\infty}^{+\infty} \lambda(u)\mathrm{d}u = +\infty$. See Survival Analysis: Overview for additional information about the use of the failure rate function.

The c.d.f., p.d.f., or the failure rate function give complete information about the distribution of a random variable having an absolutely continuous distribution. It is, however, often useful to provide a few simple characteristics or features of the distribution. Typically, one specifies the mean and the variance of the distribution. For absolutely continuous distributions, these can be computed from the p.d.f. by

$$E(X) = \int_{-\infty}^{+\infty} xf(x)\mathrm{d}x,$$

$$Var(X) = \int_{-\infty}^{+\infty} x^2 f(x)\mathrm{d}x - (E(X))^2$$

Individual Continuous Distributions

This section describes some of the most important univariate continuous distributions.

Uniform Distribution

This is a basic distribution with two parameters, a and b denoting the endpoints of an interval. The p.d.f. is given by:

$$f(x) = \begin{cases} \dfrac{1}{b-a} f & -a \leq x \leq b, \\ 0 & \text{otherwise} \end{cases}$$

If X has a Uniform (a, b) distribution, then for any interval (c, d) satisfying $a \leq c < d \leq b$, $P(c < X < d) = (d-c)/(b-a)$. The mean and variance are given by

$$E(X) = \frac{(b+a)}{2}, \quad Var(X) = \frac{(b-a)^2}{12}$$

The Uniform (0, 1) distribution is often referred to as the standard uniform distribution. If U is a random variable with standard uniform distribution, then $X = a + (b-a)U$ has Uniform (a, b) distribution. Thus, any uniform random variable can be constructed from a standard uniform random variable. This property of using standard uniform random variables to construct other random variables with specific distributions is quite general. The method is called the probability integral transform. Specifically, suppose X is a random variable with a c.d.f. given by F. Let $F^{-1}(p)$, $0 < p < 1$ denote the inverse of F defined by

$$F^{-1}(p) = \inf\{(y|F(y) \geq p)\}$$

It can be shown that if U has Uniform (0,1) distribution, then $X = F^{-1}(U)$ has c.d.f. given by F. This property is especially important in simulation studies in which one must generate a sequence of random variables with some prescribed probability distribution. If F^{-1} can be computed, then one need only generate a sequence of standard Uniform (0, 1) random variables, plug each of them into F^{-1}, and the result will be a sequence with the required distribution.

Beta (α, β) Distribution

The Uniform (0, 1) distribution is a special case of a two parameter family called the Beta (α, β) distribution. It has a p.d.f. given by:

$$f(x) = \begin{cases} \dfrac{\Gamma(\alpha+\beta)}{\Gamma(\alpha)\Gamma(\beta)} x^{\alpha-1}(1-x)^{\beta} & \text{if } 0 \leq x \leq 1, \\ 0 & \text{otherwise} \end{cases}$$

where $\alpha > 0$, $\beta > 0$, and $\Gamma(a) = \int_0^{+\infty} x^{a-1}\mathrm{e}^{-x}\mathrm{d}x$.

The Beta (1, 1) distribution is the same as the Uniform (0, 1) distribution. The mean and variance of a random variable with Beta (α, β) distribution are given by

$$E(X) = \frac{\alpha}{\alpha+\beta}, \quad Var(X) = \frac{\alpha\beta}{(\alpha+\beta)^2(\alpha+\beta+1)}$$

The Beta distribution offers a very flexible two parameter family of distributions for random variables taking values between 0 and 1. Consequently, it can often be used to model percentage or fractional quantities.

Normal (μ, σ^2) Distribution

One of the most important probability distributions is the normal or Gaussian distribution. Its p.d.f. is given by

$$f(x) = \frac{1}{\sigma\sqrt{2\pi}} \exp\left(-\frac{1}{2}\left(\frac{x-\mu}{\sigma}\right)^2\right), \quad -\infty < x < +\infty$$

The parameter μ is the mean, while σ^2 is the variance. Since the p.d.f. is symmetric about μ, this parameter is also the median.

The standard normal distribution corresponds to the case in which $\mu = 0$ and $\sigma = 1$. It has p.d.f. given by

$$f(x) = \frac{1}{\sqrt{2x}} \exp\left(-\frac{1}{2}x^2\right), \quad -\infty < x < +\infty.$$

One can construct a Normal random variable X, with mean μ and variance σ^2 from a random variable, Z, with standard normal distribution by using the relationship $X = \mu + \sigma Z$. Consequently, the calculation of the probability of an event involving X can be reduced to a calculation involving Z. For example,

$$\begin{aligned} P(a < X < b) &= P\left(\frac{a-\mu}{\sigma} < \frac{X-\mu}{\sigma} < \frac{b-\mu}{\sigma}\right) \\ &= P\left(\frac{a-\mu}{\sigma} < Z < \frac{b-\mu}{\sigma}\right) \\ &= \Phi\left(\frac{b-\mu}{\sigma}\right) - \Phi\left(\frac{a-\mu}{\sigma}\right) \end{aligned}$$

where $\Phi(x)$ is the c.d.f. of the standard normal distribution. The function $\Phi(x)$ is widely tabled and is given in nearly every basic statistics textbook.

The normal distribution is of great importance, because it is an excellent approximation for the probability distribution of many random variables that arise in nature. The reason for this

is based on the central limit theorem. This theorem states that if a random variable arises as the sum of a large number of independent random variables with a common probability distribution having a positive but finite variance, then the distribution of the sum has an approximate normal distribution; see Probability Theory: Formal for additional details. The normal distribution is widely used in the social sciences. It is often used to model the distribution of IQ and educational testing measurements within a population. It is commonly used as the distribution of the error term in regression analysis and other linear models problems; see Linear Hypothesis and Linear Hypothesis: Regression (Basics) for details. Given the importance of this distribution as a basis for much of statistical inference, in cases for which the normal dstribution does not serve as an appropriate distribution for a random variable, one often attempts to find a transformation such that the transformed variable will have an approximate normal distribution.

Exponential (λ) Distribution

The exponential distribution arises frequently in problems involving system reliability and the times between events. This distribution is most easily described using the failure rate function, which for this distribution is constant, i.e.,

$$\lambda(x) = \begin{cases} \lambda & \text{if } x \geq 0, \\ 0 & \text{if } x < 0 \end{cases}$$

The constancy of the failure rate function leads to the memoryless or Markov property associated with the exponential distribution. Specifically,

$$P(X > s + t | X > s) = P(X > t)$$

The interpretation of the above property is easiest to understand when X represents the lifetime of a component or system. The memoryless property indicates that if the component has lasted for s units of time and is still functioning, then the probability that it will last an additional t time units is independent of s. Thus, the likelihood of an additional life of at least t time units does not depend on its current age, hence the term 'memoryless.'

The p.d.f. is given by

$$f(x) = \begin{cases} \lambda \exp(-\lambda x) & \text{if } 0 \leq x < +\infty, \\ 0 & \text{otherwise} \end{cases}$$

for $\lambda > 0$.

If X has an exponential (λ) distribution, then

$$E(X) = \frac{1}{\lambda}, \quad Var(X) = \frac{1}{\lambda^2}$$

The exponential distribution is the basis for continuous time Markov chain models. This distribution is used to model the sojourn or holding time in a state for a continuous time chain; see Markov Models and Social Analysis. Moreover, the distribution is often used as a model for the time between events; for example, in modeling the arrivals of customers to a service center.

Gamma (α, λ) Distribution

The Gamma (α, λ) distribution generalizes the exponential distribution. The parameters must satisfy $\alpha > 0$ and $\lambda > 0$. The p.d.f. is given by

$$f(x) = \begin{cases} \dfrac{\lambda^\alpha x^{\alpha-1} e^{-\lambda x}}{\Gamma(\alpha)} & \text{if } 0 \leq x < +\infty \\ 0 & \text{otherwise} \end{cases}$$

Thus a Gamma (1, λ) is an exponential distribution with mean $1/\lambda$. Suppose α is an integer, and $\{X_i, 1 \leq i \leq \alpha\}$ are independent random variables, each with a Gamma (m, λ) distribution, then $S = \sum_{i=1}^{\alpha} X_i$ has a Gamma (αm, λ) distribution.

If X has a Gamma (α, λ) distribution, then

$$E(X) = \frac{\alpha}{\lambda}, \quad Var(X) = \frac{\alpha}{\lambda^2}$$

The Gamma distribution offers a two-parameter family of distributions of positive random variables with many possible shapes. This is particularly useful for modeling event histories in social science studies.

Weibull (α, λ) Distribution

Another probability distribution that arises in reliability and event history modeling is the Weibull (α, λ) distribution for $\alpha > 0$ and $\lambda > 0$. The p.d.f. is given by

$$f(x) = \begin{cases} \alpha\lambda^\alpha x^{\alpha-1} e^{-(\lambda x)^\alpha} & \text{if } x \geq 0, \\ 0 & \text{otherwise} \end{cases}$$

The failure rate function for the Weibull distribution is given by

$$\lambda(x) = \alpha\lambda^\alpha x^{\alpha-1}$$

If $0 < \alpha < 1$, then the failure rate function is decreasing, whereas if $\alpha > 1$ the failure rate function is increasing. The $\alpha = 1$ case results in a constant failure rate which corresponds to the exponential distribution.

If a random variable X has Weibull (α, λ) distribution, then X^α has an Exponential (λ^α) distribution. Thus, when $\alpha = 1$, this distribution becomes the Exponential (λ) distribution.

The Weibull distribution is often used in reliability or survival analysis (or life testing) studies. The distribution can exhibit a wide range of tail behaviors, especially heavy tails. The Weibull distribution is one of the three *extreme value distributions*, distributions which arise by normalizing the maximum of a random sample from a distribution; see Distributions, Statistical: Approximations.

Chi-Square (n) Distribution

The Chi-square distribution with n degrees of freedom has p.d.f. given by

$$f(x) = \begin{cases} \dfrac{1}{2^{n/2}\Gamma(n/2)} x^{(n/2)^{-1}} e^{-x/2} & \text{if } x \geq 0, \\ 0 & \text{otherwise} \end{cases}$$

This distribution is a special case of the Gamma (α, λ) distribution with $\alpha = n/2$ and $\lambda = \frac{1}{2}$. It arises as a sum of squares of independent standard normal random variables. Specifically, suppose $\{X_i, 1 \leq i \leq n\}$ are independent standard normal random variables, then $\sum_{i=1}^{n} X_i^2$ has a Chi-square (n) distribution.

The mean and variance of a random variable having a Chi-square (n) distribution are given by

$$E(X) = n, \quad Var(X) = 2n.$$

The Chi-square distribution is very widely used in statistics, especially in goodness of fit testing and in categorical data analysis. The distribution also arises as the distribution for the sample variance estimator of an unknown variance based on a random sample from a normal distribution.

Cauchy Distribution

The standard version of the Cauchy distribution has a p.d.f. given by

$$f(x) = \frac{1}{\pi(1+x^2)}, \quad -\infty < x < +\infty$$

This distribution is symmetric about 0; however, one can introduce both location and scale parameters which can move the center and change the concentration of the distribution.

The Cauchy distribution has a very heavy tail, comparable to the tail of the Pareto (1, c) distribution. In fact, the tail is so heavy that the distribution does not have a mean value. The Cauchy distribution is a *stable distribution*, see Distributions, Statistical: Approximations. In particular, it can arise as a properly normalized sum of independent random variables having a suitably heavy tail. The Cauchy distribution and related stable distributions have been used to model certain economic variables, especially financial asset returns.

Student $t(n)$ Distribution

The Student t distribution with n degrees of freedom arises in statistical inference problems associated with the mean of a normal distribution when both the mean and the variance are unknown. If Z and Y are independent random variables, with Z having a standard normal distribution and Y having a Chi-square (n) distribution, then the ratio nZ/Y has Student t distribution with n degrees of freedom. It has a p.d.f. given by

$$f(x) = \frac{\Gamma((n+1)/2)}{\sqrt{n\pi}\Gamma(n/2)}\left(1+\frac{x^2}{n}\right)^{-(n+1)/2}, \quad -\infty < x < +\infty$$

The Student t distribution with 1 degree of freedom is the same as the Cauchy distribution. For large n, the Student t distribution is well approximated by the standard normal distribution. The Student t distribution is widely used in the formation of confidence intervals for an unknown mean of a normal distribution estimated from a sample of data from a normal distribution with both mean and variance unknown. It also arises in the formation of confidence intervals for regression parameters; see Linear Hypothesis: Regression (Basics).

$F(m, n)$ Distribution

The $F(m, n)$ distribution arises in statistical inference problems associated with the normal distribution, especially in the analysis of variance to determine the significance of effects. If random variables V and W are independent, each with a Chi-square distribution having degrees of freedom given by m and n, respectively, then the ratio $(V/m)/(W/n)$ has an F(m, n) distribution. The p.d.f. is given by

$$f(x) = \begin{cases} \dfrac{\Gamma((m+n)/2)m^{m/2}n^{n/2}}{\Gamma(m/2)\Gamma(n/2)} \dfrac{x^{(m/2)-1}}{(mx+n)^{(m+n)/2}} & \text{if } x \geq 0, \\ 0 & \text{otherwise} \end{cases}$$

The F distribution is of great importance in the analysis of variance and the design of experiments. This distribution is used to determine the significance of different effects in an analysis of variance study; see Experimental Design: Overview; Linear Hypothesis; Analysis of Variance and Generalized Linear Models.

Pareto (α, c) Distribution

This is a two-parameter family of distributions indexed by $\alpha > 0$ and $c > 0$. The p.d.f. is given by

$$f(x) = \begin{cases} \dfrac{\alpha c^{\alpha}}{x^{\alpha+1}} & \text{if } x \geq c, \\ 0 & \text{otherwise} \end{cases}$$

This distribution has a relatively heavy tail which decreases at only a polynomial rate. Consequently, only moments of order less than α exist. In particular, if X has a Pareto (α, c) distribution, then

$$E(x) = \frac{\alpha}{\alpha-1}c, \quad \text{if } a > 1$$

and

$$Var(X) = \frac{\alpha}{(\alpha-1)^2(\alpha-2)}c^2, \quad \text{if } a > 2$$

If X has a Pareto (α, c) distribution, then the transformed random variable $\log(X/c)$ has an Exponential (α) distribution.

The Pareto distribution arises in contexts in which the tail of the distribution is relatively heavy. This occurs especially in economics; for example, in the distribution of incomes and the returns from various financial assets. The distribution also arises as the excess of a random variable over a high limit. The excess is especially important in the casualty insurance where one is interested in the excess of a claim over a high deductible limit; see Distributions, Statistical: Approximations.

Multivariate Distributions

It often happens that it is wished to consider two or more random variables simultaneously rather than individually. If $\{X_i, 1 \leq i \leq n\}$ is a set of n random variables, then each will have its own probability distribution, F_i, $1 \leq i \leq n$.This individual or marginal information does not offer insight into the relationship among these variables. To capture these relationships, one must consider the n-dimensional random vector (X_1,…, X_n). To do this, one defines the higher dimensional analogs of the c.d.f. and p.d.f. Specifically, the n-dimensional c.d.f. (or joint c.d.f.) is defined by

$$F(x_1,\ldots,x_n) = P(\{X_1 \le x_1\} \cap \ldots \cap \{X_n \le x_n\}),$$
$$\text{for } -\infty < x_i < +\infty, \quad 1 \le i \le n$$

If the joint c.d.f. is absolutely continuous, then one can define the joint p.d.f.,

$$f(x_1,\ldots,x_n) = \frac{\partial^n}{\partial x_1 \ldots \partial x_n} F(x_1,\ldots,x_n)$$

In the absolutely continuous case, one can calculate the probability of events by integrating the joint p.d.f. over the values specified by the event. When we consider the joint distribution of two random variables, (X_1, X_2), the associated joint c.d.f. and joint p.d.f. are referred to as the bivariate c.d.f. and bivariate p.d.f. A special case of this occurs when the pair of random variables has a bivariate normal distribution.

Bivariate Normal $(\mu_1, \mu_2, \sigma_1^2, \sigma_2^2, \rho)$ Distribution

The bivariate normal distribution is a special joint distribution associated with two random variables, X_1 and X_2. The joint p.d.f. of (X_1, X_2) is given by

$$f(x_1,x_2) = \frac{1}{2\pi\sqrt{1-\rho^2}\sigma_1\sigma_2}\exp\left(-\frac{1}{2(1-\rho^2)}\right)\left(\frac{x_1-\mu_1}{\sigma_1}\right)^2 - 2\rho\left(\frac{x_1-\mu_1}{\sigma_1}\right)\left(\frac{x_2-\mu_2}{\sigma_2}\right) + \left(\frac{x_2-\mu_2}{\sigma_2}\right)$$

for $-\infty < x_1, x_2 < +\infty$.

The parameters μ_i, $i = 1,2$ are arbitrary; however, the other parameters must satisfy $\tau_i > 0$, $i = 1,2$ and $-1 < \rho < +1$. When $\rho = \pm 1$, the random variables X_1, X_2 are related linearly.

If a pair of random variables (X_1, X_2) has a bivariate normal distribution with the parameters given above, then each has a marginal normal distribution, i.e., X_i has a Normal(μ_i, σ_i), $i = 1,2$ distribution. The parameter ρ is the correlation coefficient of X_1 and X_2. The bivariate normal distribution has the special property that if $\rho = 0$, then X_1 and X_2 are independent random variables. Generally, uncorrelated random variables are *not* independent.

One can represent (X_1, X_2) in terms of two independent random variables (Z_1, Z_2), each with a standard normal distribution through the relationship:

$$X_1 = \mu_1 + \sigma_1 Z_1,$$
$$X_2 = \mu_2 + \sigma_2\left(\rho Z_1 + \sqrt{1-\rho^2}Z_2\right).$$

The bivariate normal distribution arises naturally in simple regression problems, see Linear Hypothesis: Regression (Basics).

Further Reading

A large amount of material on continuous distributions, including statistical inference for unknown parameters of the distribution, is given in the text by Johnson et al. (1994). Multivariate continuous distributions are covered extensively by Johnson and Kotz (1972). Many of the above distributions are discussed in basic probability textbooks; for e.g., the text by DeGroot (1987). Some illustrations of the use of continuous probability distributions in the social sciences are given by Handcock and Morris (1999).

Abstract

Discrete probability distributions are basic to the statistical methodology for modeling and analyzing discrete (or count) data. The article first defines and discusses the main properties of discrete distributions. Usually each outcome (observation) is an integer X, known as a random variable. A distribution associates a probability (a number lying between 0 and 1) with each possible outcome; the sum of these probabilities must be unity. In distribution theory the probabilities are values of a mathematical function (usually called the probability mass function or pmf) of X. Other important functions or constants associated with a distribution that are discussed include the moments (of which the mean and the variance are the most familiar) and the probability generating function (pgf). The pmf, pgf, and moments are then given for a number of widely used distributions including the Poisson, binomial, negative binomial, logarithmic, hypergeometric, and negative hypergeometric distributions. The geneses and some typical applications of distributions are also mentioned. Ways of combining distributions to form new distributions are briefly considered. Finally multivariate discrete distributions (more than one variable is measured for each outcome) are introduced and the multinomial distribution (which is involved in the analysis of contingency tables) is examined.

Discrete probability distributions form the basis of much of the statistical methodology for modeling, analyzing, and making inferences about discrete data (sometimes known as count data). Usually each observation (outcome) is an integer; for example, the number of individuals in a family, or the number of telephone calls handled by a switchboard in a unit of time. This article is primarily concerned with these underlying distributions and their properties, rather than their applications. The article first discusses the general properties of univariate discrete distributions and then defines and examines a number of widely used distributions. Ways of combining distributions to form new distributions are briefly considered. Finally multivariate discrete distributions (more than one variable is measured for each outcome) are introduced and the multinomial distribution (which is involved in the analysis of contingency tables) is examined (*see* Multivariate Analysis: Discrete Variables, Overview).

Definitions and General Properties

Formally, a (univariate) discrete random variable (which is used to model the observation) X can take the values x_1, x_2, x_3, …. Usually these $\{x_i\}$ are restricted to be the nonnegative integers or some subset of them. For example, an investigator might assume that $\{1, 2, 3, \ldots, 20\}$ includes all the possible different values for family size that he might observe.

The (discrete) distribution of X associates with each possible X-value the probability p_x that it will be the observed value. The distribution must satisfy the two conditions:

$$0 \le p_x \le 1; \quad \sum_x p_x = 1 \qquad [1]$$

i.e., the probabilities are all nonnegative real numbers lying between zero (impossibility) and unity (certainty), and their sum must be unity because it is certain that one or other of the values will be observed. It is often convenient to assume that the number of possible outcomes (values of X) is countably infinite, i.e., there is no upper bound to X.

In discrete distribution theory the p_x, are regarded as values of a mathematical function, $p(x)$, that is usually called the probability mass function (pmf). Different functional forms lead to different discrete distributions. For example:

$$p(x) = \frac{e^{-\lambda}\lambda^x}{x!} \qquad [2]$$

is the pmf of the Poisson distribution, while:

$$p(x)\frac{n!}{x!(n-x)!}p^x(1-p)^{n-x} \qquad [3]$$

is the pmf of the binomial distribution. λ is the parameter of the Poisson distribution; this fact is sometimes highlighted by writing $p(x; \lambda)$ or $p(x|\lambda)$ instead of $p(x)$ or p_x.

There are various useful and important constants associated with a distribution. They may be used to summarize various features of the distribution. The most familiar and widely used are the moments, particularly the mean and the variance. The rth (uncorrected) moment of the distribution is defined as

$$\mu'_r = \sum_x x^r p_x \qquad [4]$$

The mean is μ'_1, the first moment of the distribution; it is conventionally denoted by μ and is used as a measure of the location of the distribution on the X-axis.

The rth moment about the mean is defined as

$$\mu_r = \sum_x (x-\mu)^r p_x \qquad [5]$$

The variance is μ_2, the second moment about the mean; it is conventionally denoted by σ^2 and is widely used as a measure of the spread of the distribution. μ_3 is sometimes used to form a measure of the degree of asymmetry of the distribution. There is a formula for μ_r in terms of the μ'_i, and vice versa.

There are other related sets of constants, such as the cumulants, the factorial moments, the factorial cumulants, which

 http://dx.doi.org/10.1016/B978-0-08-097086-8.42116-1

may be more convenient to use in some circumstances. For details of these constants, and very detailed information generally about univariate discrete distributions, see Johnson et al. (1992).

In principle all the theoretical properties of the distribution can be derived from the pmf. There are, however, several other functions from which exactly the same information can be derived. This is because the functions are all one-to-one transformations of each other, so each characterizes the distribution. One particularly useful function is the probability generating function (pgf), which is defined as

$$G(s) = \sum_x s^x p_x \qquad [6]$$

For example, the Poisson distribution has pgf:

$$G(s) = \exp[\lambda(s-1)] = e^{-\lambda} \sum_x \frac{\lambda^x}{x!} s^x = \sum_x p_x s^x \qquad [7]$$

If any function that is known to be a pgf it is expanded as a power series s, then the coefficient of s^x must be p_x for the corresponding distribution. An alternative way of obtaining the probabilities is by repeated differentiation of $G(s)$ with respect to s. If the pmf of a distribution is a complicated function and there are difficulties in computing numerical values directly, it may be possible to deduce from the pgf relatively simple relationships between successive probabilities and thus compute probabilities sequentially.

During the past half-century there has been a great proliferation of univariate discrete distributions. Patil et al. (1984) listed 136 univariate and multivariate distributions; Wimmer and Altmann (1999) list about 750 univariate distributions, but estimate the total number currently known at around 1000. While some are rather thinly disguised versions of others, in general there are important differences between distributions. Some structure can be imposed on this vast array by grouping distributions into families whose members share certain properties.

Individual Univariate Discrete Distributions

Bernoulli Distribution

This is an extremely simple and basic distribution. It arises from what is known as a Bernoulli trial: a single observation is taken where the outcome is dichotomous, e.g., success or failure, alive or dead, male or female, 0 or 1. The probability of success is usually denoted by p. The probability of failure is $1-p$ and this is often denoted by q. The distribution has the pmf:

$$p_x = p^x q^{1-x}, \quad 0 < p < 1, \quad q = 1-p, \quad x = 0, 1 \qquad [8]$$

The mean is p, the variance is pq, and the pgf is $(q+ps)$. The Bernoulli is a one-parameter distribution (the parameter is p). Two standard examples of a Bernoulli trial are (1) the toss of a coin and (2) the random selection of a ball from an urn containing a white and b black balls.

Binomial Distribution

This two-parameter distribution describes the outcome of a sequence of n independent Bernoulli trials, each with the same probability p of success. Then the probability that success is the outcome in exactly x of the trials is

$$p(x) = \binom{n}{x} p^x q^{n-x} = \frac{n!}{x!(n-x)!} p^x (1-p)^{n-x}, \qquad [9]$$
$$0 < p < 1, \quad q = 1-p, \quad x = 0, 1, 2, \ldots, n$$

This defines the binomial distribution. In terms of the two Bernoulli trials examples above, X would be (1) the number of heads in n tosses of a coin or (2) the number of white balls in a random sample of n balls selected sequentially, *provided* that each ball selected is returned to the urn before the next ball is selected; this is necessary in order that p remains constant and equal to a/n. This latter procedure is an example of sampling with replacement. The mean of the binomial distribution is np and the variance is npq. The pgf is $(q+ps)^n$. Note that this is the Bernoulli pgf raised to the nth power. This illustrates a very useful property of pgfs: if X and Y are two independent random variables whose distributions have pgfs $G_X(s)$ and $G_Y(s)$, then their sum $Z = X + Y$ has a distribution with pgf $G_Z(s) = G_X(s)G_Y(s)$.

If n is large and p is small, the Poisson distribution (see section 'Poisson Distribution') with $\lambda = np$ may be used to approximate the binomial. If n is large and p is not too close to 0 or 1, the (continuous) normal distribution may be used to construct an approximation.

The well-known chi-squared test for a 2×2 contingency table can be shown to be equivalent to a test of the difference between two binomial proportions (the proportions of 'successes' within the two classes in the table).

Poisson Distribution

This distribution occupies a central position in discrete distribution theory analogous to that occupied by the normal distribution in continuous distribution theory. It also has many practical applications. The full formal definition of the distribution is

$$p(x) = \frac{e^{-\lambda}\lambda^x}{x!}, \quad 0 < \lambda, \quad x = 0, 1, 2, \ldots \qquad [10]$$

The pgf of the distribution has the very simple form:

$$G(s) = \exp[\lambda(s-1)] \qquad [11]$$

Both the mean and the variance of the Poisson distribution are equal to λ. For small values of λ the distribution is very skewed (asymmetric) but as λ increases it becomes less skewed and is nearly symmetric by $\lambda = 15$.

The Poisson distribution plays an important part in loglinear model theory for contingency tables; the model assumes independent Poisson distributions for each cell in the table (*see* Multivariate Analysis: Discrete Variables (Loglinear Models)). Another reason why the Poisson distribution is important is that it is the distribution of events that occur randomly and independently in space or time. A classic example is the number of particles, X, recorded by a Geiger counter in a fixed time interval. This property of the Poisson means that it can act as a reference standard when deviations from pure randomness are suspected.

Geometric Distribution

If X is the number of trials *before* the first success in a sequence of Bernoulli trials with constant p, then:

$$p_x = pq^x, \quad 0 < p < 1, \;\; q = 1 - p, \;\; x = 0, 1, 2, \ldots \qquad [12]$$

The probabilities form a geometric progression, hence the name.

The mean is p/q, the variance is p/q^2, and the pgf is $p(1 - qs)^{-1}$.

Just as the Bernoulli distribution is a special case of the binomial distribution, the geometric distribution is a special case of the negative binomial distribution (NBD) (see section 'Negative Binomial Distribution').

Some authors define X to be the number of trials up to and *including* the first success; the pmf is then $p_x = pq^{x-1}$, X ranges over the positive integers, and the pgf is $ps(1 - qs)^{-1}$.

Negative Binomial Distribution

The negative binomial distribution is a widely used alternative to the Poisson distribution for handling count data when the variance is appreciably greater than the mean (this condition is known as overdispersion and is frequently met in practice).

The pmf of the NBD is

$$p_x = \binom{k + x - 1}{x} p^x q^x, \quad 0 < k, \;\; 0 < p < 1, \quad q = 1 - p, \;\; x = 0, 1, 2, \ldots \qquad [13]$$

The mean is kq/p, the variance is kq/p^2, and the pgf is $p(1 - qs)^{-k}$.

In the literature, several different parameterizations of the distribution are found. A common one uses $Q = 1/p$ and $P = q/p$. It follows that $p > 0$, $Q = 1 + P$, and:

$$p_x \binom{k + x - 1}{x} \left(1 - \frac{P}{Q}\right)^k \left(\frac{P}{Q}\right)^x \qquad [14]$$

When $k = 1$, the NBD becomes the geometric distribution. When k is a positive integer, the NBD is sometimes known as the Pascal distribution; it can then be interpreted as the distribution of the number of failures before the kth success (i.e., X is the sum of k independent geometric random variables). This kind of model is known as a waiting time distribution.

There are several other models that lead to the NBD. A classic example arises from the theory of accident proneness that was developed during and after World War I. It was assumed that the number of accidents suffered by an individual was distributed as a Poisson distribution, but that the Poisson parameter λ (interpreted as the individual's accident proneness) varied between individuals in the population under study. If λ is assumed to follow the (continuous) gamma distribution, then the NBD is the resultant overall distribution of accidents per individual. This model has been applied to retail purchasing, absenteeism, doctor's consultations, among many others. The model reflects a type of heterogeneity in the population. A different type of heterogeneity occurs when there is clustering. If it is assumed that the number of clusters is distributed as a Poisson, but the number of individuals in a cluster is distributed according to the logarithmic distribution (see section Distributions Without a Zero Class), then the overall distribution is a NBD.

The existence of these and other models means that the NBD is used to model many different types of data. The penalty for this ubiquity is the difficulty in inferring which underlying model applies.

Distributions without a Zero Class

In some applications the meaningful outcomes do not include $X = 0$. Examples are the size of a family and the size of a cluster of dwellings. Such cases require distributions that start at $X = 1$. One way of achieving this is to take a distribution that is defined for $x = 0, 1, 2, \ldots$ and truncate the term $X = 0$. In order to form a valid distribution from the remaining probabilities, it is necessary to adjust them upwards by a factor of $(1 - p_0)^{-1}$ so that the second condition in [1] is satisfied. For example, the zero-truncated Poisson distribution has pmf:

$$p_x = \frac{e^{-\lambda}\lambda_x}{x!(1 - e^{\lambda})}, \quad 0 < \lambda, \;\; x = 1, 2, 3, \ldots \qquad [15]$$

Alternatively, there are some distributions for which the pmf is not defined for $X = 0$. One of these is the logarithmic distribution, with pmf:

$$p_x = \frac{\theta^x}{-x \log_e(1 - \theta)}, \quad 0 < \theta < 1, \;\; x = 1, 2, 3, \ldots \qquad [16]$$

The mean is $a\theta/(1 - \theta)$ and the variance is $a\theta(1 - a\theta)/(1 - \theta)^2$, where $a = -1/\log_e(1 - \theta)$. The pgf is

$$G(s) = \frac{\log_e(1 - \theta s)}{\log_e(1 - \theta)} \qquad [17]$$

This distribution can model data distributions with very long tails.

Hypergeometric Distribution

A key feature of the binomial distribution is its representation in terms of a sequence of independent Bernoulli trials with fixed p. In many practical situations, however, p is not constant due to dependence between successive Bernoulli trials. In the derivation of the binomial using the ball in an urn model (b), each selected ball was returned immediately to the urn (sampling with replacement) so p was always equal to $a/(a + b)$. However, if each selected ball is retained and not returned, then p changes after every trial; this is sampling without replacement. The resultant distribution is hypergeometric with pmf:

$$\begin{aligned} p_x &= \binom{a}{x}\binom{b}{n - x} \Big/ \binom{a + b}{n} \\ &= \binom{n}{x}\binom{a + b - n}{a - x} \Big/ \binom{a + b}{a}, \\ & x = 0, 1, 2, \ldots, \min(n, a) \end{aligned} \qquad [18]$$

The mean is $na/(a + b)$ and the variance is $nab(a + b - n)/(a + b)^2(a + b - 1)$. The pfg is

$$G(s) = \frac{{}_2F_1[-n, -a; b-n+1; s]}{{}_2F_1[-n, -a; b-n+1; 1]} \quad [19]$$

i.e., the ratio of two classical Gaussian hypergeometric functions.

An important use of the hypergeometric distribution is in the analysis of 2×2 contingency tables; the probability of a result as extreme as the observed result is given by the tail of a hypergeometric distribution. This is known as Fisher's exact test; it is frequently recommended for use instead of the chi-squared test when the smallest expected frequency is less than 5.

Beta-Binomial (Negative Hypergeometric) Distribution

In the section 'Negative Binomial Distribution' heterogeneity of the Poisson parameter λ was allowed for by assuming that λ had a gamma distribution. The resultant Poisson–gamma distribution was in fact the NBD. Analogously, when there is heterogeneity in the binomial parameter p one way of allowing for it is to assume that it follows the (continuous) beta-distribution – a flexible distribution on the interval (0, 1). The resultant beta-binomial distribution has pmf:

$$p_x = \binom{-a}{x}\binom{-b}{n-x}\Big/\binom{-a-b}{n}, \quad 0 < a,\ \ 0 < b,\ \ n \text{ is an integer}$$
$$= \binom{a+x-1}{x}\binom{b+n+x-1}{n-x}\Big/\binom{a+b+n-1}{n}, \quad x = 0, 1, 2, \ldots n \quad [20]$$

The mean is $na/(a+b)$, the variance is $nab(a+b+n)/(a+b)^2(a+b+1)$, and the pgf is

$$G(s) = \frac{{}_2F_1[-n, a; -b-n+1; s]}{{}_2F_1[-n, a; -b-n+1; 1]} \quad [21]$$

The distribution is also known as the negative hypergeometric or inverse hypergeometric distribution. Like the NBD, it can be interpreted as a waiting time distribution.

Combinations of Distributions

New distributions may be created from existing ones. Two major methods have been mentioned in the sections 'Negative Binomial Distribution' and 'Beta-Binomial (Negative Hypergeometric') Distribution. The process of allowing the parameter of one distribution to itself be distributed (as in the derivation of the NBD by letting the Poisson parameter λ be distributed as a gamma variable) is known as mixing (in earlier literature the term compounding was commonly used). Many other mixture distributions appear in the literature.

The process exemplified by the NBD cluster model of Poissonly distributed clusters with logarithmically distributed cluster sizes has been given several names including compounding and generalizing, both of which are ambiguous; a clearer terminology that is frequently used nowadays is to call the resultant distribution a randomly stopped-sum or stopped-sum distribution. If the pgf of the distribution of clusters is $g(s)$ and that of the cluster size distribution is $h(s)$ then the pgf of the resultant distribution has the very simple structure:

$$G(s) = g(h(s)) \quad [22]$$

Various properties of the stopped-sum distribution can be deduced via this relationship.

These processes are one reason why there are so many different discrete distributions in the literature. They often arise from attempts to model processes in applications. Clearly some distributions like the NBD that are mixtures are also stopped sums, but this is not always the case. As mentioned previously, the existence of fundamentally different ways of deriving the same distribution can raise serious problems in practice when trying to make causal inferences from data.

Multivariate Discrete Distributions

The move from distributions of one variable to joint distributions of several variables is complicated by the existence of relationships (dependencies) between the variables. This is reflected in the complexity of the structure of the multivariate pmf and related functions. Furthermore, there may be more than one way of representing dependency; more than one bivariate version of a particular univariate distribution may be constructed. Often the multivariate pgf is one of the simpler ways of defining and characterizing a distribution, A bivariate pgf is defined as

$$G(s_1, s_2) = \sum_{x,y} p_{x,y} s_1^x s_2^y \quad [23]$$

the definition of a multivariate pgf is a straightforward extension.

The multinomial distribution has pgf and pmf:

$$G(s_1, s_2, \ldots, s_r) = (p_1 s_1 + p_2 s_2 + \ldots + p_r s_r)^n \quad [24]$$

$$p(x_1, x_2, \ldots,) = \frac{n!}{x_1!, x_2!, \ldots, x_r} p_1^{x_1} \ldots p_r^{x_r} \quad [25]$$

When $r = 2$ it becomes the binomial distribution. All the marginal distributions of the multinomial are binomials. The conditional distribution of $(X_2, X_3, \ldots X_r)$ given X_1 is also multinomial.

One of the first reference texts to be devoted to the multivariate area was Kocherlakota and Kocherlakota (1992). They set out the general theory of bivariate discrete distributions and considered in detail the properties of bivariate versions of the major univariate distributions. Johnson et al. (1997) give a very thorough treatment of the current position in multivariate discrete distributions; the general theory is given and a wide range of distributions are examined.

Johnson et al. (1992) is the standard reference text for univariate discrete distributions; all the univariate distributions above are considered in detail, together with very many more.

Diversification, Relatedness, and the New Logic of Co-Creation

David J Teece, University of California, Berkeley, CA, USA; and Berkeley Research Group, Emeryville, CA, USA

© 2015 Elsevier Ltd. All rights reserved.

This article is a revision of the previous edition article by R.A. Lowe and D.J. Teece, volume 6, pp. 3574–3578, © 2001, Elsevier Ltd.

Abstract

Diversification involves the expansion of an enterprise into new markets of various types. This article focuses on cross-industry diversification. Conglomerate (unrelated) diversification, in which a business entity groups together a disparate bundle of businesses, has generally fallen out of favor, except in developing economies, where it remains a viable response to local institutions. Related diversification has come to be understood in the strategic management literature as the reapplication of some of the enterprise's slack resources, which are hard to monetize in other ways, to new opportunities. There is a large, but disputed, literature claiming that diversification on average reduces performance compared with comparable single-business firms. Diversification as a growth strategy may be in decline due to the prevalence of outsourcing, strategic alliances, and platform-based ecosystems.

Introduction

Diversification is an aspect of the growth of an enterprise in which it expands into new activities or markets. The new activities may share some technical or market resource with the enterprise's current operations (related diversification); may integrate a previously external upstream or downstream activity relative to current operations (vertical integration); or may be wholly unrelated (conglomerate diversification). The expansion can be accomplished through acquisition or by internally developing a new line of business.

Expansion into foreign markets is another type of diversification. Although it shares some characteristics with the industry-level diversification considered here (e.g., two countries can be culturally 'close' in much the same way that two industries can be technologically 'close'), there are also critical differences. In particular, scholars are less likely to suspect that international diversification results from managerial malfeasance than they are to suspect industry diversification. The international diversification literature is not explicitly discussed in this article.

There is a vast and growing literature concerning industry-level diversification. Reviews of this literature (e.g., Wan et al., 2011) exist elsewhere, so this article does not attempt to be comprehensive. Rather, it highlights some of the key concerns of the literature about diversification, with an emphasis on the concept of relatedness.

Conglomerate (Unrelated) Diversification

Conglomerate diversification, in which a firm enters (most often by acquisition) a line of business that has no obvious market or technological relationship to its existing activities, was popular in the 1960s. One possible reason is that antitrust enforcement was relatively strict with respect to vertical and horizontal mergers during that time (Mueller, 1969).

The conglomerate wave may also have been driven by a belief that good management ability could be profitably (and easily) applied to any industry, a belief that is no longer as widely held. For instance, GE, one of the last major conglomerates, has started leaving its executives in single-business units for longer periods of time to allow them to develop deep industry expertise instead of moving them across different units every few years (Linebaugh, 2012).

Most conglomerates have since been unwound. The leveraged buy-out wave of the 1980s was in part fueled by the desire of many firms to shed lines of business.

Today, more companies seem interested in specialization than in the questionable opportunities afforded by unrelated, or even vertical, diversification. Advances in transportation and telecommunications have greatly reduced the negative aspects of working across great distances. As a result, it is often simpler and less expensive to outsource parts of a firm's activities to the lowest cost-qualified vendors, wherever they are located in the world, than to develop (or maintain) internal capabilities.

A countercurrent to the overall trend toward a narrow focus for the business enterprise is business groups located in developing countries, where they may undertake anything from sugar to textiles to software. This may be a response to the unique institutional and techno-economic conditions in these countries, where personal contacts can be more important than industrial capabilities (Kock and Guillén, 2001). As enterprise capabilities improve and/or the local economy becomes more open to foreign competitors, local business groups need to adjust their structure or suffer the consequences. The experience of Korean business groups provides examples of groups that collapsed (e.g., Daewoo) when the economy came under stress and others (e.g., Samsung) that have thrived (Kim et al., 2004).

Understanding Diversification

In the (neoclassical) version of economic theory, with perfect competition and homogeneous firms, there is neither benefit to, nor penalty for, diversification. Economic rents are competed down to zero in all industries.

In the finance literature, diversification is viewed through the principal-agent framework as a manifestation of mismanagement and is predicted to be destructive of firm value.

Although there is some empirical evidence in support of the finance view on average, there are market imperfections that create profitable opportunities for firms to diversify.

The mainstream economic rationale for efficient diversification involves assuming economies of scope (Panzar and Willig, 1981). Scope economies occur when the cost of producing a given quantity of two or more different products is lower when they are produced jointly rather than separately. Although this could give rise to firms diversifying into the joint products, scope economies can potentially be realized through contracting between separate producers. Hence, as a matter of theory, if markets function properly, economies of scope can be captured without joint ownership. It is only when the scope economies are based on sharing specialized assets, such as know-how, that capturing economies of scope requires diversification (Teece, 1980).

There are also cases where firms will choose to diversify vertically in order to create a cospecialized upstream or downstream linkage that would be hard to replicate contractually. For example, Apple created its own chain of brick-and-mortar stores so it could control completely its look and feel and ensure that Apple products and the company's image are well represented by sales staff.

As an alternative approach to understanding diversification, strategic management scholars in the 1980s developed the Resource-Based View of the firm. The Resource-Based View was built on a major work by Edith Penrose (1959) on the growth of the firm. In Penrose's model of enterprise growth, companies always found themselves with potentially valuable underutilized resources. Provided that the necessary human resources were not prohibitively scarce, management could find and pursue other lines of business in which the slack resources could be profitably deployed.

Although Penrose's ideas found little acceptance among mainstream economists, they were eventually embraced by scholars of strategic management such as Teece (1982) and Wernerfelt (1984). Among other things, the Resource-Based View amplified on Penrose's idea that firm-specific resources used in one industry could provide a basis for competing profitably in others where their attributes would also help create value.

There is historical case-study evidence in support of this theory. Chandler (1969) described how the Depression in the United States triggered the first great wave of diversification. General Electric and Westinghouse expanded from light and power equipment to household appliances, and General Motors expanded into diesels, tractors, and airplanes.

The resource-based approach has produced numerous testable hypotheses. To take just one example, a statistical study by Chatterjee and Wernerfelt (1991) showed that the nature of a firm's resources affects its type of diversification. Excess physical- and knowledge-based resources were more likely to be associated with related diversification, while excess internal financial resources were associated more closely with unrelated diversification.

Resources also have implications for the performance of diversified firms, about which more is said below. Douglas Miller (2006) developed a resource measure called technological diversity that records the dispersion of industries to which a company's patent portfolio is applicable. He found that, for a given level of technological diversity, a diversified firm will create more value than a comparable cluster of single-business firms.

An advantage of the account of diversification offered by the Resource-Based View over those used in mainstream economics is that it can account for all types of vertical and lateral diversification. Even in the case of conglomerate diversification that is seemingly unrelated to a firm's previous activities, the resources of management and finance know-how constitute a bridge to the new, unrelated activity.

The key notion underlying this approach is the resource. Resources are firm-specific assets that may be difficult for rivals to imitate. They could be tangible but are most valuable when intangible. Examples include intellectual property, process know-how, customer relationships, and the knowledge possessed collectively by groups of skilled employees. Organizational knowledge, while firm specific, is seldom limited only to the products and processes with which it is actively involved (Teece, 1982).

Intangible resources are difficult to trade because their property rights are likely to have fuzzy boundaries, and their value is dependent on their use in the context of the firm's other resources and assets. As a result, such resources are typically not traded at all. They are also generally difficult to transfer to other firms.

A management team, finding itself with slack corporate resources and knowing they are nearly impossible to trade in isolation, is likely to look for other activities where it can profitably redeploy the resources. The effectiveness of this redeployment is a reflection of management's competence in recognizing and seizing opportunities, which are, in turn, part of the organization's dynamic capabilities (Teece, 2007).

The Profiting From Innovation framework (Teece, 1986), which integrates insights from transaction cost economics, strategic management, and other fields, identified a richer set of factors that could impact diversification decisions in the context of innovation. The Profiting From Innovation framework posits that firms need to control and own complementary assets so as to capture returns from innovation in certain circumstances. In particular, incentives to diversify are stronger when the innovation has weak intellectual property protection around its core technology. Firms need to control only the (vertical or horizontal) complements to their core activity that are scarce (or likely to become so post-entry) and thus apt to siphon away profits from the firm's activities.

Empirical Research: Measuring Diversification

In practice, many different types of diversified companies exist. In order to develop a useful theory of diversification, efforts have been made to measure the interbusiness relatedness of diversified corporations. But the challenges are significant.

The most common approach, developed by Caves (1981), uses the hierarchy implicit in the 4-digit Standard Industrial Classification (SIC) system, the predecessor to the 6-digit North American Industry Classification System (NAICS), so that businesses in different 4-digit industries but the same 3-digit industry are 1 'unit' apart, whereas businesses whose closest connection is their 2-digit industry memberships are 2 'units' apart, and so forth. Lemelin (1982) measured interindustry

relatedness as the correlation coefficient across input structures taken from the input–output table. Klavans' (1989) index of technology relatedness is also based on input patterns, but he uses the amount of overlap in occupational categories as an index.

A fairly noisy measure of relatedness has been developed by Gollop and Monahan (1989); they compute the dissimilarity between the patterns of input shares, using nine classes of input (i.e., production wages, fuel, purchased services, etc.). Working with Census of Manufacturers data, they argue that because the data are "filtered through the SIC system, the underlying notion of product dissimilarity must have a supply-side orientation … differences in distribution systems and/or marketing patterns are ignored. It follows that the formulation of product heterogeneity must be based wholly on technical considerations" (1989: p. 4).

Teece et al. (1994) developed an index using SIC data that went beyond input considerations and overturns Gollop and Monahan's dictum. This was accomplished by moving away from measuring the properties of SIC industries and instead looking at the frequencies with which they are combined in firms. When a pair of industries were combined into a single firm, the two industries were assumed to be related in some meaningful way. The 'coherence' of a diversified firm does not mean that all of the firm's activities are mutually interrelated but, rather, that there is evidence of pairwise interrelatedness among them. This approach is consistent with the resource-based theory that a firm expands into a new line of business when it sees an opportunity to reapply some of its resources from an existing line.

Using this measure of coherence on a sample of US corporations, Teece et al. (1994) found that as firms grow more diverse, the overall coherence of each firm does not change much, but there are large differences in coherence among firms. They proposed that the differences could be

> explained as a complex interaction between three classes of factors: (1) enterprise learning, which we suggest is a 'local' phenomena; (2) evolutionary paths, which we see being shaped both by where firms have been (in terms of their scope of their past activities), where they are now (their current competences and complementary assets), and the opportunities which lie ahead; and (3) the strength of competition and the mechanism firms have to shield themselves from it, whether in the product market or the capital market. (1994: p. 28)

They found that the 'coherent diversifiers' driven by these factors were the most common corporate mode in their sample.

Diversification has also been treated as a multidimensional construct. The industries into which a firm has diversified can be related by technology, supply base, skill base, physical asset base, customer base, management knowledge, or, more likely, some combination. Different types of relatedness appear to have different performance effects (Pehrsson, 2006).

Empirical Research: Diversification and Performance

Empirically, some diversification – especially into related industries – appears to improve performance by various accounting measures. But as the diversification spreads into still more industries, performance declines beyond some point. This inverted-U shape may reflect that continued expansion into new industries will eventually render top management less able to control and integrate its operations effectively (Palich et al., 2000).

A number of studies using comparisons of nondiversified firms have found that diversification, broadly defined, destroys value. If true, this result would support the finance theory perspective that diversification involves managerial actions that may be inconsistent with shareholder interests. Most studies in this line of research do find that diversified firms perform worse than specialized firms in the same industries, based on comparisons of market value either to corporate assets ('Tobin's q') or to a hypothetical nondiversified value based on the median market values of single-industry firms in each of the relevant industries.

Relatedness may mediate the effect. Wernerfelt and Montgomery (1988) and Berger and Ofek (1995) found that, among diversified firms, those with the most closely related activities had the best performance. But more recently, Hoechle et al. (2012) found that a performance discount still exists even for diversified firms whose divisions are so related that they share a 4-digit NAICS code.

A few studies (e.g., Campa and Kedia, 2002) found that the diversification discount for all firms becomes insignificant once the self-selection of firms that diversify and the firms they acquire has been controlled for. The result suggests that firms are most likely to diversify or merge when they are weak to begin with or under duress of some kind. This accords with the Depression case-history evidence cited earlier. A further wave of diversification occurred during the Second World War in response to a different kind of market stress, namely a large jump in demand for new products from the military and from consumer industries seeking to replace raw materials that had suddenly become scarce.

Yet more recent studies, with access to additional years of data, have been unable to replicate the self-selection results. Hoechle et al. (2012) found a large and significant valuation discount even after applying a self-selection method similar to that of Campa and Kedia (2002). They went on to show that as much as one third of the discount can be explained by a set of 14 measures of the quality of corporate governance, once again raising the possibility that diversification results, on average, from inefficient investment choices by management. This is in line with articles showing that internal capital markets – far from allowing managers to allocate funds more efficiently than the market (as suggested by Williamson, 1975) – are prone to underinvest in promising divisions while cross-subsidizing weak ones instead of forcing them to improve (see, e.g., Ozbas and Scharfstein, 2010).

However, the existence of a diversification discount remains an unsettled point open to various critiques. For example, the segment designations in Standard & Poor's Compustat database of corporate financial information, on which all of these studies have been based, have been called into question. A study that used establishment-level data from the Census Bureau to derive a more accurate measure of diversification found a diversification *premium* instead of

a discount (Villalonga, 2004). Another study explored evidence that stock market investors might value any group of single-industry firms more highly than a diversified firm with equivalent cash flow, a result that separates the diversification discount from any management implications (Mitton and Vorkink, 2010). Clearly, there is more scope for research on the existence and interpretation of the diversification discount.

Conclusion

The production-oriented logic that once drove the classic form of industrial diversification has receded in importance in many economies. As noted above, waves of specialization and globalization have transformed the world economy by enabling the outsourcing of business functions. Thus the leading electronics company, Apple, owns no factories of its own and expanded into the media-distribution business by building a platform that serves as the basis of an ecosystem encompassing the world's major media sources. As this example suggests, internal diversification is eschewed as a mechanism to achieve productive efficiency. Rather than diversification, what is required is the assembly of a business ecosystem to help co-create new markets. An implication is that the simple production theory approach to understanding diversification cannot capture the richness of the complementarities and externalities that are necessary to understand the efficiency of the activity boundaries chosen by particular firms.

Diversity and Disagreement in Ethics: Philosophical Implications

Michele M Moody-Adams, Columbia University, New York, NY, USA

© 2015 Elsevier Ltd. All rights reserved.

Abstract

The extraordinary variety of ethical beliefs and practices that is possible within and across human societies has been a rich source of philosophical reflection. This article discusses important philosophical accounts, historical as well as contemporary, of what that diversity and disagreement come to. Philosophers ask what diversity and disagreement can tell us about the nature of ethical argument and inquiry, and they consider the implications of diversity and disagreement for ethical practice and social life. It is shown that philosophical contributions to these debates have often shaped and, in turn, been shaped by related work in the social sciences, and that as a result philosophers and social scientists frequently discuss similar methodological concerns. It is also argued that some of those concerns demand a response to debates about the nature of argument and inquiry in science, in order to address skepticism about the possibility of ever resolving serious ethical disagreement. Finally, it is shown that many recent philosophical discussions of diversity and disagreement address the ongoing challenge of adjudicating ethical and political conflict in culturally complex societies.

Diversity and Disagreement

The extraordinary variety of beliefs and practices that is possible within and across human societies has been a rich source of philosophical reflection. This article focuses on philosophical accounts of specifically ethical diversity and disagreement. Philosophers want to know what ethical diversity and disagreement might tell us about the nature of ethical argument and inquiry, as well as to consider the implications of diversity and disagreement for ethical practice and political institutions. This article discusses the most influential philosophical treatments of these issues, drawing on historical as well as contemporary accounts. It will be shown that these accounts have often shaped and, in turn, been shaped by related work in the social sciences, and that as a consequence they have frequently given rise to similar methodological worries. It will also be shown that these accounts will continue to be shaped by concern about how best to understand argument and inquiry in natural science, as well as by increasingly urgent worries about how to adjudicate ethical and political conflicts in culturally complex societies.

The extraordinary variety of ethical beliefs and practices that is possible within and across human societies, along with the ethical disagreement to which that variety frequently gives rise, has been a rich source of philosophical reflection. Philosophers have sought to understand the nature and causes of ethical diversity and disagreement, as well as what that diversity and disagreement might reveal about the nature of ethical argument and inquiry. They have investigated the similarities and differences between ethical inquiry and other kinds of inquiry, particularly scientific inquiry, and asked what the relevant similarities and differences can tell us about the nature of rationality. They have also analyzed the implications of ethical diversity and disagreement for ethical practice, and for the foundations of social and political life.

The Nature and Sources of Ethical Diversity and Disagreement

Philosophical Understandings of Anthropological and Sociological Evidence

Philosophical awareness of ethical diversity is as old as philosophy itself. It is evident in the ancient Greek beginnings of Western philosophy – particularly in the ethical and political thought of Plato and Aristotle. In the early and middle *Dialogues* of Plato (1961), for instance, exchanges between the Platonic Socrates and his interlocutors reveal many of the ethical conflicts and debates, and hence the ethical diversity and disagreement, that helped to shape the social and political life of fourth-century BC Greece. A generation later, Aristotle's sensitivity to the concrete contexts of deliberation and action, detailed in the *Nichomachean Ethics* and the *Politics*, reflected an even richer understanding of social and political diversity, and of the resultant complexity of ethical belief and practice. Neither Plato nor Aristotle believed that ethical diversity and disagreement required us to relinquish a commitment to ethical objectivity. But this stance was in marked contrast to that adopted by some of their philosophical forebears, especially fifth-century BC sophists such as Protagoras and Gorgias, to whom Plato's philosophy was in part a response. Moreover, the objectivist conceptions defended by Plato and Aristotle were met by the emergence of a powerful current of skepticism. This development culminated in the Academic skepticism of Cicero, and especially the second-century AD Pyrrhonian skepticism of Sextus Empiricus, in which ethical diversity and disagreement inevitably raised the specter of ethical relativism.

The sixteenth-century rediscovery and dissemination of Sextus' writings coincided with the beginnings, in the West, of a period of extraordinary exploration and economic expansion. Both developments were important in shaping the rise of early modern Western philosophy in the late sixteenth and early seventeenth centuries. European exploration and expansion

produced a body of literature purporting to offer a richer picture of human ethical variety than anything to be found in ancient philosophical texts. These accounts had a profound effect on early modern thinkers who pondered the nature and sources of ethical variety. Thinkers such as Montaigne (1958) came to accept the indispensability to philosophy of what we would now call sociological or anthropological explanations of ethical diversity. But, deeply influenced by the Pyrrhonian skepticism he found in Sextus, Montaigne also insisted that fully appreciating the details of human ethical diversity would always lead a reasonable person to accept ethical relativism. Montaigne thus rejected the claims of philosophers, from Plato onward, who believed that one could render the existence of ethical diversity and disagreement compatible with ethical objectivism.

In the seventeenth, eighteenth, and early nineteenth centuries, debates about the implications of ethical diversity and disagreement – based primarily on the testimony of explorers, settlers, and economic adventurers – continued to shape philosophical reflection about ethics. That reflection took one of its most interesting forms in Montesquieu's *Persian Letters* (1973 [1724]), in which Montesquieu's potentially dangerous criticisms of ethical and political life in eighteenth-century France are presented to the reader as the contents of letters written home by two fictional Persian visitors. But with the rise of modern anthropology in the late nineteenth and early twentieth centuries, philosophical reflection about diversity and disagreement took on a new tone. Philosophers were gradually persuaded by the claims of anthropology to provide expert testimony – rooted in theoretically sophisticated empirical research, rather than idiosyncratic personal or economic interests – about the nature and extent of diversity and disagreement across cultures and social groups.

Yet the cultural ascendancy of anthropological claims about diversity also reinvigorated the skeptical challenge to ethical objectivism. Ruth Benedict's Patterns of Culture (1934) provides an instructive and influential expression of this development. Benedict claimed to have given ethical relativism a scientific foundation for the first time. Some philosophers were prepared to accept this account of the matter and to cede authority for assessing the claims of relativism to empirical social science. But Benedict's claims of a newly 'scientific foundation' for relativism may be difficult to sustain. Her formulation and defense of relativism seem simply to reiterate Montaigne's argument that we have "no other test of truth and reason than the example and pattern of the opinion and customs of the country we live in." Melville Herskovits (1972) went on to argue that modern anthropology finally provided "tough-minded" empirical support for claims about the "ethnocentrism" of objectivist analyses of ethical disagreement. But Herskovits's efforts to defend charges of ethnocentrism do not go much beyond Montaigne's contention that "each man calls barbarism whatever is not his own practice." The fact that so many familiar defenses of relativism predate the rise of modern anthropology has led some philosophers to wonder whether ethical relativism is simply a reasonable inference from ethical diversity and disagreement, or a pre-theoretical assumption that unreflectively predetermines the way some in which some theorists go on to characterize the data of diversity.

Yet other philosophers have undertaken detailed investigation to show the value and importance of anthropological study to philosophical reflection about ethics. Some have conducted their own ethnographic studies of the ethical beliefs and practices of Native American groups, in an effort to determine the empirical reliability of anthropological accounts (Brandt, 1959; Ladd, 1957). Others – spurred on, in part, by the late work of Ludwig Wittgenstein, especially by the concept of 'forms of life' in his *Philosophical Investigations* (1978) – have interrogated the theoretical underpinnings, as well as the broader philosophical implications, of the social scientist's claims about diversity and disagreement (Wilson, 1970; Winch, 1972). These efforts introduced important new empirical detail into philosophical discussions of the extent of cultural diversity – details drawn, most famously, from the work of E.E. Evans-Pritchard on the Azande (1937), and from the work of Edmund Sapir (1985 [1949]) and Benjamin Whorf (1956) on the conceptual variety embedded in human languages. The resulting debates raise new and controversial philosophical questions about the nature of ethical disagreement – particularly the question whether human ethical systems could ever contain wholly incommensurable ethical (or other) concepts. Philosophical attempts to understand the origins and causes of ethical diversity and disagreement have frequently relied on generally utilitarian or consequentialist accounts of that diversity. On these accounts, ethical practices (and their associated beliefs) come into existence, and continue in existence, primarily because they serve the aims of the groups that develop them. From the eighteenth century forward, such accounts are usually linked with essentially evolutionary hypotheses about the development of ethical practices. The ethical and political thought of David Hume, for instance, attributes the rise of particular ethical practices to unconscious, or unintended, processes that are vaguely akin to natural selection. But accounts of the processes in question usually have more in common with Herbert Spencer's theory of social evolution than with Darwin's claims about the role of natural selection in biological evolution. William Graham Sumner's *Folkways* (1907) – which combined evolutionary ethics with a forceful defense of ethical relativism – contains what became one of the most influential expositions of just such a view.

Methodological Concerns about the Idea of Fundamental Disagreement

During the mid-twentieth century, many philosophers accepted the claims of relativist anthropologists that the data of comparative anthropology could firmly ground an argument for meta-ethical relativism: the view that there is no rational method for adjudicating between the conflicting ethical claims of different cultures. Yet as many of their critics objected the mere facts of ethical diversity and disagreement within and across cultures cannot be sufficient to establish the truth of ethical relativism (in any form). The objection is that merely from the fact of cultural variability we cannot confidently conclude that any resultant ethical disagreements will necessarily be disagreements in fundamental ethical commitments between which no rational adjudication is possible, and establishing this conclusion is essential to establishing the plausibility of ethical relativism.

This objection points to a way in which ethical relativism may, in fact, be fundamentally underdetermined by all available empirical evidence. For it is at least possible, as the psychologist Karl Duncker argued, that principles of ethical valuation might remain 'invariant' across the most diverse cultures, even while the 'situational meanings' of the acts, traits, and states of affairs subject to ethical evaluation could vary dramatically across those same cultures (Duncker, 1939). In short, cross-cultural ethical diversity might be properly traced not to differences in fundamental ethical principles but to cultural variation in derivative ethical principles – that is, to principles embodying local understandings of how to apply fundamental ethical principles to particular actions, character traits, and states of affairs. Thinkers who claim to identify fundamental ethical disagreement must, therefore, be able to show that they have identified a conflict between genuinely fundamental ethical principles or beliefs, and not between derivative principles or beliefs intended to apply the more fundamental principles or beliefs. Further, as the philosopher R.B. Brandt once noted, it is very difficult to find two cultures, or even two individual people, who can be shown to attribute identical nonmoral properties to some action, trait, or state of affairs and who nonetheless give the relevant action, trait, or state of affairs different ethical valuations (Brandt, 1959, 1967).

Identifying these difficulties does not prove that it is impossible to find convincing evidence of genuinely fundamental ethical disagreement. Brandt himself claimed to have found at least one such disagreement, in spite of the methodological difficulties he believed to attend any effort to do so (Brandt, 1959). Moreover, the demand for conceptual clarity in defining a disagreement as 'fundamental,' rather than 'derivative,' is difficult to meet, because distinguishing fundamental from derivative ethical beliefs and principles is no simple matter. In particular, it is not clear how to find a criterion for describing a belief or principle as fundamental or derivative that does not presuppose a commitment to some fairly complex elements of an ethical conception – that is, to ethical notions that may themselves be the subject of considerable controversy and disagreement. Yet in coming to appreciate the methodological and conceptual difficulties inherent in attempts to establish fundamental ethical disagreement, the empirical researcher and the philosophical interpreter alike are reminded that there are important obstacles to surmount if one seeks to draw a supportable inference for meta-ethical relativism from the fact of cross-cultural disagreement.

Individual Uncertainty and the Roots of Ethical Pluralism

Reliance on the evidence of cross-cultural variability is not the only means – or even the most important means – by which philosophers have sought to understand the nature and sources of ethical diversity and disagreement. According to some philosophers, the decision-making processes of an individual agent experiencing ethical uncertainty can sometimes tell us as much (if not more) about the nature and sources of ethical diversity and disagreement than the comparative anthropologist's claims about cross-cultural conflict. On these accounts, when a sincere and reflective agent attempts to choose between equally compelling, but conflicting and even apparently irreconcilable, ethical ends, what that agent typically confronts is the fundamental plurality and diversity (and, on some views, sometimes even the ultimate incommensurability) of available and plausible ethical ends. Pluralists such as Isaiah Berlin (1969) and Charles Taylor (1985) believe that philosophers like Plato, along with those of his intellectual descendants who would defend the unity of ethical value, simply fail to understand that plurality and diversity are intrinsic features of ethical value. According to the ethical pluralist, ethically compelling ends and purposes cannot all be reduced to a single measure of ethical value; nor can they all be realized in a single life. This means that even the sincere and reflective agent (or, perhaps, especially the sincere and reflective agent) will eventually confront what Thomas Nagel has called the fragmentation of ethical value (Nagel, 1979).

Those who understand ethical value as intrinsically plural and diverse thus have a way of explaining diversity in the beliefs and practices of various cultural and social groups in terms that go beyond any available on the standard anthropological account. On a pluralist conception of ethics, cross-cultural ethical diversity is simply an important – and essentially unavoidable – reflection of the fundamental plurality and diversity of ethical value itself. More controversially, some ethical pluralists go on to assert that neither individual human beings nor cultures and societies can escape fundamental ethical conflict – conflict, that is, between irreconcilable or incommensurable fundamental ethical principles and concepts. But some of the same difficulties inherent in the effort to defend the thesis of fundamental conflict across cultural groups, particularly the challenge of defining the contrast between derivative and fundamental ethical principles and beliefs, will attend any effort to show that no individual agent can avoid fundamental ethical conflict.

Following the lead of Isaiah Berlin (1969), some pluralists contend that any individual agent who claims to experience no fundamental ethical conflict is in some way rationally deficient, or else deeply self-deceived. Yet there are many conceptions of human flourishing (both secular and religious) which purport to make fundamental ethical conflicts effectively impossible by identifying or articulating a single 'dominant end' – as John Rawls has described it – to which all other human ends must be subordinate, and with respect to which the subordinate ends can be unified. Such conceptions, particularly when combined with a willingness to allow other agents to reject them, have often been thought to embody defensible understandings of rational choice and rational agency. Moreover, some ardent defenders of the view that dominant-end conceptions of human flourishing are in some way deficient or irrational actually acknowledge that these conceptions do not intrinsically violate principles of rational choice. But they nonetheless insist that there remains something ultimately incomplete, or perhaps even irrational, about a life lived in accordance with such a conception (Rawls, 1971; Hampshire, 1983). In response to such assertions, the question of whether a compelling defense of ethical pluralism requires a commitment to the inescapability of fundamentally irresolvable ethical conflicts – across social

and cultural groups, or in individual lives, or both – remains a subject of lively philosophical debate (Gowans, 1987; Stocker, 1989; Moody-Adams, 1997).

Implications of Disagreement for Understanding Ethical Argument and Inquiry

Historically, philosophers have held quite differing views about what the facts of ethical diversity and disagreement might tell us about the nature of ethical argument and inquiry. The standard views can be divided up in terms of the position they take with regard to the objectivity of ethics – that is, with regard to the question whether there can be at least some right answers to ethical questions, where the rightness of the answer is independent of human beliefs and practices. But there is great variety within both the objectivist and the nonobjectivist positions, particularly with regard to important epistemological questions (questions of whether and how we can have moral knowledge) and serious metaphysical concerns (concerns about the existence or non-existence of objective value entities).

Varieties of Ethical Objectivism and Serious Ethical Disagreement

The most familiar variety of ethical objectivism is *absolutist ethical objectivism*, on which there is at most one right answer to any given ethical question, and according to which the ethical correctness of that answer does not depend upon human beliefs and practices. Plato's *Republic* contains one of the most fully developed and widely influential versions of this conception. The 'Allegory of the Cave,' in Book Five of the *Republic*, richly depicts the underlying epistemological and metaphysical assumptions. According to the allegory, the inhabitants of a cave who remained chained to a wall, seeing only the shadows of real things by the light of a humanly built fire, are deprived of any possibility of rationally understanding what is real, and their beliefs and practices reflect their ignorance. Only the person who is released from ignorance and illusion by being unchained, and allowed to leave the cave, can become capable of a rational appreciation of the real essences of things as illuminated by the genuine light of the sun. The metaphysical commitments associated with this view – in Plato's doctrine of the Forms – are developed in surrounding passages in the *Republic*, and in other Dialogues like the *Symposium* and the *Phaedrus*. On the resulting view, what the relativist takes to be fundamental ethical diversity and disagreement is simply a function of moral ignorance rooted in the tendency to our experience of imperfect copies and shadows of the real as though they might reveal the essence of the ethical.

But absolutist ethical objectivism need not involve this kind of metaphysical realism about value entities existing independent of human belief and practice, or even any kind of realism about independently existing value entities or antecedently given moral facts. Nor need it involve the potentially problematic epistemological assumptions needed to explain how anyone might come to know the Form of the Good, and why so few seem genuinely capable of doing so. Immanuel Kant held a constructivist conception of ethical objectivity, on which humanly constructed practices (and their underlying beliefs and assumptions) are objective when they have been constructed in accordance with what Kant took to be the objectively valid (and already known) supreme principle of morality, the Categorical Imperative. In its most basic formulation, the Categorical Imperative directs the agent to act only on those policies (reasons) that he or she could will to serve as universal laws of action. What the relativist identifies as fundamental ethical disagreement is for Kant simply evidence that one or more parties to the disagreement has failed to subject the policy underlying a practice or a proposed course of action to the rational scrutiny required by the Categorical Imperative.

Some ethical pluralists believe that ethical objectivism need not be linked with the kind of absolutism found in the work of Plato or Kant. But whether ethical pluralism is indeed compatible with ethical objectivism remains a subject of rich, and ongoing, philosophical debate. How far can the pluralist go in rejecting the absolutist's 'one right answer' approach and remain an ethical objectivist? Many think that the most plausible pluralist candidates for the label 'ethical objectivist' are forms of ethical pluralism that recognize the possibility of diverse answers to disagreements involving derivative principles, yet retain the 'one right answer' approach to analyze disputes involving fundamental principles. Of course, any such views must confront the problem of reliably distinguishing fundamental from derivative ethical principles. Moreover, while there is no evidence that this problem is not, in principle, capable of a compelling solution, some ethical pluralists avoid the problem altogether by defending a limited and moderate relativism. On these accounts, the relativist rightly posits the possibility – and the frequent occurrence – of at least some fundamentally irresolvable ethical disputes.

Varieties of Nonobjectivism and Serious Ethical Disagreement

Meta-ethical relativism is, perhaps, the most familiar form of ethical nonobjectivism. Its main claim, as noted above, is a negative thesis about the impossibility of rationally adjudicating (purportedly) fundamental ethical disagreements. But some meta-ethical relativists also attempt to defend a normative ethical relativism that makes a positive claim about the content of morality and about the nature and sources of ethical disagreement. In its bolder formulations, normative ethical relativism asserts the 'equivalence' of all ethical practices and beliefs. This version of the view has some important implications for a relativist approach to ethical practice – most often resulting in a demand to 'tolerate' all ethical practices as 'equally valid.' According to more modest versions of normative ethical relativism, we cannot confidently assert the superiority of one ethical stance over another with which it somehow conflicts, and we should therefore withhold judgment as a recognition of ethical uncertainty.

Meta-ethical relativism starts from the facts of ethical diversity and disagreement, but some forms of nonobjectivism posit very different explanations of those facts. One such view is ethical subjectivism, according to which ethical claims are fundamentally statements about the individual speaker's subjective feelings (not about the practices of a particular

social or cultural group). What the relativist identifies as a fundamental ethical disagreement is, for the ethical subjectivist, simply evidence of the deep-rooted feelings of the parties to the dispute. Yet both meta-ethical relativism and ethical subjectivism allow that ethical statements have some cognitive content. On the subjectivist views, ethical statements tell us something meaningful and informative about the feelings of the speaker – and indirectly about the feelings of any similarly constituted persons. On meta-ethical relativism, in contrast, ethical statements tell us what members of a particular social or cultural group believe to be good – and, ultimately, about the local social worlds in which ethical practices arise and have their (limited) application (Williams, 1985).

It is important that some nonobjectivist views find ethical claims to be cognitively substantive, because there are varieties of nonobjectivism that deny that ethical statements have any cognitive content at all. The most influential and controversial such view is the theory of emotivism, first articulated in the early twentieth century by A.J. Ayer (1946). According to Ayer, fundamental ethical judgments (he called them "pure judgments of value") are nonrational, noncognitive expressions of emotion that cannot be true or false. Even the apparently most serious ethical disagreement, for Ayer, is not much different from a round of energetic 'boos' and 'yeas' for the opposing teams at a sporting event. Ayer's critics charged that such claims appear to deny that ethical disagreements ever occur. Ayer's efforts to mollify his critics were problematic: moral disagreements occur, he responded, but only as disagreements "without formal contradiction." This hypothesis can be confirmed, he urged, by the tendency for the parties to such disagreements to resort to "mere abuse" when arguments fail.

The Infirmity of Ethics Compared with Science?

Ethical Disagreement as a Source of Skepticism about Ethical Methods

Yet despite its counterintuitive claims about ethical disagreement, and its implausibly narrow understanding of what it is to have cognitive content, emotivism was a powerful and challenging embodiment of skepticism about the rationality of ethical argument and inquiry – a skepticism firmly rooted in the frequent intractability of ethical disagreements. There is a special irony in the fact that emotivism seems to deny the reality of the very phenomenon underwriting its skeptical challenge to the methods of ethics. But for many philosophers, even those who would explicitly reject emotivist understandings of ethical language, the emotivist's challenge to ethics retains a certain potency. The continued existence of intractable ethical disagreements, for these thinkers, is evidence (along with the explanatory and predictive success of science) that ethics, in the words of logician and philosopher of science W.V.O. Quine, is "methodologically infirm" compared with science.

Alternatives to Skepticism

Yet the conception of science as the arbiter of rationality, capable of supplying standards that must be met by any domain of rational argument and inquiry, has been challenged. Its critics object that it wrongly presumes that all domains of human inquiry might have the same aim. They maintain that ethics and science are fundamentally different kinds of enterprises – one claiming to explain and predict natural phenomena, the other seeking to help us to lead lives worth living – and that there is no reason to expect similarities between the methods of ethics and the methods of science. To be sure, some ethicists continue to search for fundamental similarities between the methods and aims of ethics and science. But their critics urge that such efforts can only make ethics look like a poor and distant relation of science, and that we distort the aims and purposes of ethics by trying to make it conform to structures of argument in science. Still further, these critics reject the notion that the persistence of disagreement in ethics – even intractable disagreement – is intrinsically a sign of the failure of ethical methods. Might it not be, they ask, that in some domains of human argument and inquiry disagreement is an important catalyst for serious reflection, and a crucial stimulus to avoiding smugness and self-righteousness?

Implications of Ethical Disagreement for Practice

The Merits and Demerits of Tolerance

The existence of ethical diversity and the persistence of ethical disagreement nonetheless pose important difficulties for ethical practice. How are we to respond to those whose ethical beliefs and practices differ, sometimes quite substantially, from our own? The ethical objectivist will argue that in some or even all ethical disputes, one or more parties to the dispute has made some kind of error in moral reasoning or perception. Ethical relativists, and some pluralists, who argue for tolerance in response to ethical disagreements, urge that the objectivist response is too frequently associated with moral smugness and moral self-righteousness, and potentially dangerous and culturally imperialist ethnocentrism. But these associations are not intrinsic, and the demand for tolerance poses its own dangers when it functions (as it sometimes has) to sanction local practices that involve the violent coercion of innocent victims, or murderous intolerance of internal cultural dissent. The demand for tolerance also raises urgent questions about theoretical consistency. If it is intended as a nonrelative demand, incumbent on any agent, then it is clearly incompatible with the relativist stance. If it is aimed only at the inhabitants of some societies – say Western liberal societies – then it violates relativist structures in demanding the extension of what may well be a locally compelling principle to an intercultural context. Still further, uncritical tolerance of ethical diversity and disagreement must not be confused with respect for cultural diversity. Many philosophers urge that we sometimes show the greatest respect for diverse ways of life by being ready to engage in open and noncoercive discussion with those who represent them.

The Dangers and Incoherence of Ethical Isolationism

Some relativists are so concerned about the dangers of ethnocentrism and the imperialist overreaching of some cultures that

they insist on an ethical isolationism. According to the ethical isolationist, cultural outsiders can never understand ethical practices and beliefs associated with a genuinely unfamiliar way of life, and thus have no rational basis for any kind of critical reflection on – let alone outright criticism of – those practices and beliefs. But ethical isolationists typically defend their views by detailing their own special understanding of the practices and beliefs of the unfamiliar 'other,' richly conveying facts about those practices and beliefs in order to convince other cultural outsiders of the limits of their understanding. This tack shows how difficult it is to defend ethical isolationism except in terms that reveal the inconsistency and implausibility of the view.

Pluralism and Multiculturalism

Yet philosophers who reject ethnocentrism, relativism, and isolationism must still confront the persistence of ethical diversity and disagreement and the challenges they pose, especially in the culturally complex societies found in large, modern nation-states. An increasingly influential response, associated with some forms of ethical pluralism, is the doctrine of multiculturalism, which in its most familiar form recommends that we act and judge on the presumption that the ethical beliefs and practices of every way of life are in principle valuable and worthy of respect. But compelling philosophical discussions of multiculturalism have construed this presumption as, at best, a 'starting hypothesis,' maintaining that a final verdict on the worth of any practice must always await the results of respectful, but sustained, critical reflection (Taylor, 1992). In response, some philosophers have urged adoption of a critical multiculturalism (as a form of objectivist ethical pluralism) that leaves open the possibility that reflection on almost any practice might generate rationally compelling grounds on which to reject the practice as ethically indefensible (Moody-Adams, 1997).

The question of how to put multiculturalism into practice has also been a central topic of debate in contemporary ethical and political philosophy. Some theorists have developed a model of 'multicultural citizenship' for culturally complex liberal democracies that is centered around formal political accommodation of cultural minorities (Kymlicka, 1996; Modood, 2007). These efforts have generated resistance from theorists who cite conflicts with the individualist assumptions of liberal political philosophy, and with the secular neutrality thought to be central to the most familiar variants of liberal thought. In other contexts, political debates about whether the idea of nationality can be separated from the idea of a single defining ethnic and cultural heritage continues to generate controversy about the possibility of a politically robust multiculturalism (Parekh, 2002). The challenge of moving beyond the theoretical and practical dimensions of this impasse between multiculturalism and its critics will remain an important element of normative ethics and political philosophy in the twenty-first century.

Diversity in organizations

Jorge A Gonzalez and Azadeh Zamanian, University of Texas-Pan American, Edinburg, TX, USA

Abstract

The study of diversity in organizations addresses the implications of workplace diversity from social justice, legal compliance, and organizational performance standpoints. Diversity in groups and organizations is associated with social categorization and information/decision-making processes, which respectively are related to adverse and beneficial attitudes and behaviors. Diversity scholars have attempted to shed light into these mixed results by addressing the role of categorical and relational demography, diversity types, curvilinear and interactive effects, and complex conceptualizations of diversity. Diversity management strategies, such as affirmative action and management-led diversity initiatives, have been designed to reduce discrimination and stimulate the beneficial effects of diversity.

Diversity refers to the extent in which members of an entity, such as a group or organization, differ from one another. This encompasses a very broad range of individual attributes, although most attention has been given to differences in gender, race/ethnicity, and age. Diversity in attributes, such as nationality, culture, education, function, tenure, ability, sexual orientation, religion, values, personality, goals, and many others is gaining attention. The field is mainly concerned with the outcomes and management of individual differences in organizational settings, including work groups and organizations. Its importance lies on the fact that the workplace in many nations is growing increasingly diverse. For instance, women and racial and ethnic minorities now constitute the majority of workers in the USA (Bureau of Labor Statistics, U.S. Department of Labor, www.BLS.gov).

Diversity and the Goals of Its Study

Most diversity research addresses the implications of workplace diversity taking a social justice, legal compliance, or organizational performance standpoint. Social justice goals include the reduction of bias and discrimination, and the enhancement of inclusion in the workplace. These objectives center on increasing the presence and inclusion of traditionally underrepresented or disenfranchised social groups: women, racial/ethnic minorities, and older workers. The social justice perspective includes the study of workplace discrimination and the implementation of diversity management programs. Such programs may be designed to meet legal compliance goals, such as following affirmative action and equal opportunity legislation. Nonetheless, diversity management also includes management-led diversity initiatives, which tend to be motivated by social justice objectives, and designed to stimulate the inclusion of a range of social backgrounds broader than the one established by the law.

Organizational performance goals rely on the value diversity offers to organizations (Cox and Blake, 1991). Consistent with the 'business case' for diversity or 'value-in-diversity' hypothesis, some scholars suggest that diversity is a source of sustained competitive advantage and leads to greater organizational performance. For instance, with basis on the resource-based view of the firm, organizational racial diversity is considered a resource that is valuable, rare, and difficult to imitate and thus a source of sustained competitive advantage (Richard, 2000). These ideas emphasize the benefits organizations draw from their compatibility with constituents in a complex and diverse environment, such as potential employees, business partners, and customers. Therefore, social justice, legal compliance, and performance goals are not necessarily incompatible. Government legislation, such as affirmative action emphasizes the accomplishment of social justice goals through legal compliance. Moreover, the 'business case' for diversity is based on the appeal of the idea that organizational performance and social justice goals are compatible.

Diversity Outcomes

Despite the appeal of the business case for diversity, reviews of the literature have revealed that diversity in groups and organizations has the potential for both positive and negative outcomes (van Knippenberg and Schippers, 2007; Williams and O'Reilly, 1998)

These seemingly paradoxical results have been synthesized into two theoretical perspectives: social categorization and information/decision making. The social categorization perspective describes how people categorize themselves and others into groups to make sense of a complex environment. It relies on social identity and social categorization theories, which posit that people display in-group favoritism in their social interactions. These theories are complemented with the similarity-attraction paradigm, which holds that people are attracted to others who possess similar psychological attributes, but infer similarity through observable demographic attributes. Diverse groups and organizations are subject to faulty social categorization processes and therefore have more affective conflict than homogeneous ones (Ashkanasy et al., 2002), as well as lower trust, communication, cooperation, helping, cohesiveness, satisfaction, and commitment. For these reasons, diverse groups and organizations may ultimately perform poorly in comparison with homogeneous ones.

In contrast, the information/decision-making perspective holds that diversity is related to a wider range of, skills, abilities, expertise, and perspectives (Cox and Blake, 1991; Watson et al.,

1993). This variety in knowledge provides a broad cognitive resource base that permits greater creativity and innovation in group tasks and decision making. For instance, diversity reduces the possibility of groupthink – a premature consensus or conformity that leads to poor decisions. Instead, diversity enhances the opportunities for dissent, debate, the rise of a devil's advocate, and other factors associated with substantive or beneficial task-related conflict. In effect, this can lead to better decision making. For instance, divergent viewpoints in a team can result in team reflexivity – a careful consideration of its functioning – which can lead to increased team learning and effectiveness. Overall, diverse groups and organizations have the opportunity to be more effective thanks to a broader cognitive base.

An integration of these two perspectives suggests a more nuanced consideration of diversity and the intervening processes that lead to its attitudinal, behavioral, and performance outcomes. Different individual attributes may present different processes and outcomes, and a combination or interaction of such attributes may present complex processes. Diversity effects may also be contingent on a variety of moderators or contextual circumstances. Furthermore, it is important to consider that diversity is a compositional construct, meaning that it is an attribute of groups and organizations rather than individuals, but individual-level dissimilarity from others also has an important role in the field.

Categorical and Relational Demography

Research about diversity at the individual level of analysis is concerned with simple demographic effects, as well as the extent in which an individual is similar or different from referent others. The simple or categorical demography approach assesses the behaviors associated with specific individual attributes. This would include, for example, the study of the behavior associated with being Hispanic or comparing the attitudes or managerial attributes of men and women at work.

The relational demography approach refers to the extent in which an individual is different in an attribute or category from referent others, such as other members of a work group or a particular person (Riordan, 2000). Relational demography studies typically take the social categorization perspective. Most studies have found that people who are different from others tend to be less committed to their organizations and satisfied with their jobs, and more likely to be absent and quit their jobs (e.g., Tsui et al., 1992). Studies concerned with dyads show similar results. For instance, being demographically different from a supervisor is related to lower employee commitment, a more adverse relationship, and lower assessment of employee performance from such supervisor (e.g., Tsui and O'Reilly 1989). Relational demography includes the effects tokenism, or being extremely different from others in a group, such as of being the sole woman in an otherwise completely male group. Tokenism emphasizes the particular effects of visibility and suggests the adverse effects of dissimilarity not only depend on the feelings, thoughts, and demographic identity salience of the token person, but also on the way that other group members perceive and treat such person.

Relational demography can be combined with categorical demography and group diversity to cross levels of analysis in its study. Such interaction approach can reveal asymmetrical social group effects. For example, relational demography studies have shown that being different in terms of gender or race is typically more detrimental to work attitudes for men and Whites than for women and non-Whites (e.g., Tsui et al., 1992). Interestingly, Chatman and O'Reilly (2004) found that women were more likely than men to be affectively attached to same-gender groups, but that women were also more likely to leave same-gender groups. This was attributed to status, which was higher in male-dominated groups. The interactive approach can combine categorical and relational demography effects with organizational-level diversity. This would suggest that relational demography effects depend on organizational diversity and would likely present weaker adverse effects in heterogeneous organizations.

Diversity Typologies

As stated earlier, diversity encompasses a broad range of individual attributes. Many diversity studies focus on a single attribute (e.g., 43% of diversity studies reviewed by Jackson et al., 2003). One reason may be that scholars and managers are often interested in a single dimension of diversity. For instance, people are often seen as having either gender or a race, but not both. Nonetheless, diversity scholars and managers are increasingly paying attention to a multiplicity of individual attributes to answer the question of whether all differences make a difference. This has given rise to individual attribute typologies.

One typology describes whether individual attributes are task related or not. In this case, differences in education, function, and tenure provide a variety of task-related information, whereas differences in race/ethnicity, gender, and age do not (Pelled et al., 1999). The rationale behind this distinction is that task-related diversity stimulates substantive conflict, which drives people to consider multiple points of view, perspectives, and opinions, while nontask-related diversity leads to affective conflict that can be detrimental.

Another typology differentiates across surface- and deep-level diversity. Surface-level diversity refers to differences in observable demographic attributes, such as race, ethnicity, gender, and age, while deep-level diversity refers to differences in psychological attributes, such as personality traits, beliefs, and values (Harrison et al., 1998). This distinction holds that both surface- and deep-level diversity may harm group social integration, cohesion, and in effect performance. However, the effects of surface-level diversity weaken through time, while those of deep-level diversity become stronger as group members get to know one another. This typology diverges from early conceptualizations of organizational demography, which assessed cognitive (deep-level) diversity in management groups using demographic (surface-level) attributes as a proxy.

Despite the logical appeal of typologies, meta-analyses that have studied them, particularly the task/nontask distinction, have not provided conclusive results (e.g., Horwitz and Horwitz, 2007). These meta-analyses either have not shown different outcomes for task and nontask diversity on group cohesion and performance, or have found inconsistent evidence about the role of social integration processes. These inconclusive results stimulated the development of the

categorization-elaboration model, which suggests that both task and nontask diversity dimensions affect the elaboration of task-related information and social categorization processes (van Knippenberg and Schippers, 2007). A more recent meta-analysis exploring specific attributes rather than a task/non-task typology showed more nuanced effects. Functional and educational backgrounds were positively related to team creativity, innovation, and performance, while educational diversity was related to performance only in top management teams. Also, racial and sex diversity had small adverse effects on performance (Bell et al., 2011). Another meta-analysis suggested that the main effects of various forms diversity was small, but that its effect were strong once contingent moderators and contextual circumstances were considered (Joshi and Roh, 2009).

The Role of Context and Moderators in Diversity Effects

The role of diversity on behavior and performance depends on a variety of contextual factors. Meta-analytic data have showed that the main or direct effect of diversity attributes on team performance is very small, but that this relationship is much stronger when the role of contextual factors is incorporated (Joshi and Roh, 2009). Such contextual factors and moderators include industry setting, team interdependence, team longevity, leadership, task complexity, regulatory pressure, and market competition, among others. For instance, diversity is likely to lead to better outcomes when transformational leadership is high, and when teams are interdependent. Also, empirical evidence, particularly from laboratory studies, suggests that diverse groups tend to perform better than homogeneous ones in complex and creative tasks, while homogeneous groups perform faster and better in routine tasks.

The degree of diversity itself is a contextual factor that shapes its outcomes. Diversity can present curvilinear effects on attitudes and performance that are U-shaped, or even J-shaped. In other words, adverse outcomes may be present at moderate levels of diversity, but moderate diversity may not present such outcomes or even have positive effects at very high levels. For example, managerial racial diversity has a curvilinear, U-shaped association with organizational financial performance (Richard et al., 2004). Similarly, a study of cultural heterogeneity in multicultural teams found that moderate levels of diversity were associated with lower team performance, while highly homogeneous and highly heterogeneous teams presented lower social categorization problems. These effects were further contingent on team longevity (Earley and Mosakowski, 2000), suggesting that, given time, highly diverse teams tend to de-emphasize their demographic differences and form a hybrid team culture or common in-group identity.

Diversity in one type of attribute can also influence or moderate the effect of another attribute or type. For instance, diversity in deep-level attributes, such as values, personality, or time urgency can increase the effects of demographic diversity on attitudes, conflict, and performance (e.g., Jehn et al., 1999). Also, a collective culture – an aggregation of shared values that emphasize cooperation – can reduce demographic diversity effects on conflict (Chatman et al., 1998).

An organization's diversity climate also moderates diversity effects. Diversity climate refers to the shared organizational member perceptions of the fairness of the organization's diversity-related structural characteristics and values. A positive or inclusive diversity climate can counter the adverse effects of relational demography on workplace attachment, particularly for people of color. It can also enhance the positive effects of diversity on performance (Gonzalez and DeNisi, 2009; McKay et al., 2007). Diversity climate is similar to the concept of diversity perspectives or paradigms. Ely and Thomas (2001) described three different diversity perspectives, which refer to the manner in which organizational members express and manage diversity-related tensions. The discrimination-and-fairness perspective is present when organizational members believe that the point of diversity initiatives is to reduce discrimination and enhance fairness. In contrast, an access-and-legitimacy perspective consists of beliefs that the goal is to tap diverse markets more effectively. Also, an integration-and-learning perspective is present when people believe that cultural differences drive diverse knowledge and insight, and this third perspective is associated with the greatest degree of effectiveness (Ely and Thomas, 2001). In other words, a diverse organization is likely to perform better when its members believe that cultural differences drive diverse knowledge and insight than when members assume that diversity is only valuable to gain niche markets or to avoid blatant discrimination and lawsuits. The notions of diversity climate and perspective are similar to diversity culture (Cox and Blake, 1991) and mind-set (van Knippenberg and Schippers, 2007).

The effects of organizational racial and gender diversity on financial performance also depend on environmental factors. Consistent with the social categorization perspective and requisite variety arguments, racial and gender diversity-performance effects tend to be stronger in the service than in manufacturing. One reason may be that diverse firms are better able to best serve a diverse stakeholder and customer base. Studies addressing the role of diversity in organizational financial performance (Richard et al., 2004) also report a stronger positive relationship between racial diversity in firms that have an innovation strategy, have a narrow span of control, are in their early life cycle stages, and operate in munificent environments. Studies that have considered community demographics as context and explored the match between organizations and community demographics have reported both positive and negative effects on attitudes and performance (Joshi and Roh, 2009).

Complex Conceptualizations of Diversity

Complex conceptualizations of diversity include the combination or alignment of various attributes or types. This includes diversity faultlines, a correlation of multiple individual attributes that provide a clear basis for subgroup differentiation (Lau and Murnighan, 1998). For example, a group comprised of young, African-American men and older, White women shows the combination of three different attributes into subgroups. Diversity faultlines are related to heightened conflict, less communication, lower learning, and disrupted group functioning.

Diversity typically refers to the variety or dispersion or variety in terms of a specific individual attribute. However, it may also refer to separation or disparity (Harrison and Klein, 2007).

Separation refers to differences in position or opinions, such as in values, beliefs, or attitudes. A group that is fragmented due to different values or polarizing opinions would be an example. Disparity refers to vertical differences in the proportion of valuable assets and resources held by unit members, which acknowledges the important role of power and status differences. An example would be a group with inequitable pay or network access. Combinations of these three types are possible. For example, members of an ethnically diverse group may hold values that are similar within each ethnic group but distinct across ethnic groups, showing ethnic variety and value separation. Such ethnically diverse group could also present no differences in pay, which would mean having high variety but low disparity.

Diversity Management

The potential for positive, negative, and complex effects from diversity warrants efforts to manage diversity. Diversity management refers to the development and implementation of practices, processes, and systems designed to enhance workplace diversity, exploit its benefits, and minimize adverse outcomes. Diversity management includes affirmative action policies, which aim to comply with the law, as well as management-led diversity initiatives, which refer to formalized human resource management practices designed to reduce bias and discrimination, promote and sustain organizational diversity, and improve performance. Affirmative action predates the notion of diversity management, and many diversity scholars and consultants differentiate across them. The reason is that the focus of affirmative action is to comply with a legal mandate, while diversity management seeks to increase organizational performance, fairness, equality, and inclusion through management-led initiatives. Nonetheless, some scholars refer to management-led diversity initiatives as 'voluntary' affirmative action programs. A source of benchmarking on diversity management is the Web site and magazine DiversityInc, which publishes a list of the top companies who champion diversity (DiversityInc, www.DiversityInc.com).

Affirmative Action

Affirmative action refers to activities taken to reduce discrimination and provide employment and promotion opportunities for disenfranchised groups. Affirmative Action was initially enacted for US government contractors through executive orders by President Kennedy and Johnson in the 1960s, and was expanded by the Civil Rights Act of 1964. Title VII of the civil rights act prohibited organizations with more than 50 employees from discriminating on the basis of race, color, religion, sex, or national origin. It also established the Equal Employment Opportunity Commission (www.EEOC.gov) to oversee the law. Related legislation has been expanded to cover age, disability, pregnancy, veteran status, genetic information, and sexual orientation. The goal of affirmative action was to compensate for past discrimination, prevent ongoing discrimination, and provide equal employment opportunities to covered demographic groups. Similar antidiscrimination laws have been passed in many other countries. For example, Canada's Employment Equity Act covers 'visible minorities' (language and religion – relevant to Canada's English and French heritage – are invisible attributes), women, people with disabilities, and Aboriginal peoples. Also, Malaysia's New Economic Policy protects the majority Malay population, who traditionally has had lower access to business and income opportunities than the Malaysian Chinese minority.

Scholars and practitioners have discussed issues with employee acceptance of affirmative action. Some argue that the legal coercive pressure of affirmative action may neutralize rather than enhance equality. This occurs because affirmative action promotes the idea that beneficiaries are hired due to preferential treatment rather than their qualifications. For this reason, affirmative action can be associated with a stigma of incompetence among beneficiaries and associated feelings of unfairness on the part of the majority group. Other scholars posit that different programs have different degrees of perceived fairness and acceptance. In general, programs that promote hiring gain greater acceptance than other programs, such as those involving promotions, compensation, and training. In addition, program beneficiaries (e.g., African-Americans) typically report greater acceptance of affirmative action programs, particularly beneficiaries who report to have experienced discrimination before (Kalev et al., 2006).

Management-Led Diversity Initiatives

Unlike affirmative action, management-led diversity initiatives and other diversity management practices focus on reducing discrimination and improving the effectiveness of diversity organizations by changing its practices, culture, and climate. Diversity initiatives may be inclusive of individual attributes that are not covered by law. They are likely to emphasize the inclusion and of all social groups, including the majority group. Many diversity initiatives are designed to increase competitive advantage (Cox and Blake, 1991). Also, they may be designed to underscore the importance of acknowledging the uniqueness of employees and social group members as individuals, rather than their assimilation into the dominant culture (Shore et al., 2011). Despite their voluntary nature, management-led diversity initiatives may also have a backlash. For instance, employees may become distrustful or cynical and resist the implementation of diversity programs if prior efforts have failed in the past (Kalev et al., 2006). Examples of management-led diversity initiatives include targeted recruitment, retention, promotion, mentoring, and diversity training.

Organizations use a variety of targeted recruitment strategies to attract women and minority job applicants to increase diversity. For instance, organizations may adopt impression management techniques, such as displaying pictorial diversity and inclusive policy statements in their job marketing, recruiting from colleges with a large minority population, and employing female and minority recruiters (Avery and McKay, 2006). Research shows similarity-attraction race effects in job interviewer–applicant dyads, and that these effects influence interview quality, the interviewer's evaluation of the applicant, and the applicant's perceptions of the organization's diversity-related attributes. Gender effects are also present, but these tend

to be confounded with interpersonal attraction in cross-sex recruiter–applicant dyads. Recruitment suggestions from the literature include the use of structured interviews, which can serve to minimize the potential for bias in job interviews and applicant assessment. The use of employee informal networks may help the recruitment of women and minorities in organizations that already have some diversity. Workplace diversity initiatives also focus on retention. This is important due to the positive relationship between diversity and turnover, and because women and people of color in general turn over at a higher rate than Whites and men. Retention efforts may also be necessary after targeted recruitment, since failing to meet the expectations of an unrealistic job preview may result in future turnover (Avery and McKay, 2006).

Diversity management also includes efforts to promote of women and racial/ethnic minorities into management positions. This can be meant to break the 'glass ceiling', which traditionally referred to the lack of top-level managerial-level representation of such groups. Mentoring is a strategy meant to stimulate such promotions. It refers to a formal developmental relationship between an individual (protégé) and a senior employee (mentor). Some perspectives favor same-gender and same-race mentoring for women and people of color because a common background tends to lead to a better mentoring relationship. For instance, women in same-sex mentoring relationships have more social interaction than in cross-sex relationships (Ragins and Cotton, 1999). Other perspectives favor cross-sex and cross-race mentoring in male and White-dominated settings to provide access to network contacts, power, and opportunities that otherwise would not be available. Regardless of the demographics, results from mentoring studies suggest that women and people of color protégés experience higher quality relationship and better career outcomes from informal than from formal mentoring.

Diversity training refers to formal efforts to enhance skills and knowledge about diversity. Diversity training programs may include the objective to provide employees with information about legal issues (e.g., equal opportunity laws and sexual harassment), increase employees' awareness and sensitivity to backgrounds other than their own, and develop communication and interpersonal skills helpful in diverse settings. The success of diversity training has been evaluated on a number of factors, such as the demographics of the trainer and training content. For example, diversity training designed to build skills tends to be evaluated better than programs intended to inform about legal compliance requirements or raise awareness. Factors associated with the adoption and perceived training success include the support of top management, mandatory attendance, evaluation of results, rewards for increasing diversity, and an inclusionary diversity definition (Rynes and Rosen, 1995).

A review of diversity initiatives stated that programs that established management responsibility – such as affirmative action, diversity committees, and diversity management positions – were more strongly associated with organizational managerial diversity than mentoring, networking, diversity training, and diversity audits or performance evaluations. Moreover, organizations with diversity initiatives establishing responsibility obtained better effects from diversity training and evaluations (Kalev et al., 2006).

Research Trends

The study of diversity has shown that diversity in groups and organizations has the potential for both positive and negative effects on attitudes, behavior, and performance. Meta-analytic data have shed some light into the manner different diversity attributes and types influence these outcomes (e.g., Bell et al., 2011), but a synthesis of these results is still inconclusive. These mixed results suggest that empirical efforts to explore the role of contextual moderators and to understand the processes involved in diversity effects will continue. The study of interactive and complex effects involving different diversity types, multiple levels of analysis, and faultlines hold the most promise. For instance, studies of faultlines could pay attention to various combinations of diversity attributes and types to reveal which combinations present the most harmful effects, and which combinations stimulate beneficial processes and outcomes. One should note that much research has been conducted from a US perspective, but diversity is a global issue. Studies that explore diversity in different nations and pay attention to their local demographics and relevant social conditions are likely to uncover novel diversity-related issues.

Division of Labor: History of the Concept

Richard Sturn, University of Graz, Graz, Austria

© 2015 Elsevier Ltd. All rights reserved.

Abstract

Division of labor involves the decomposition of processes of (re)production, wealth creation, and knowledge development into various tasks, each of which is performed by a separate individual or collective agent. Division of labor is related to other important concepts, such as capital accumulation, growth, specialization, dynamically increasing returns to scale, and social differentiation. Types of division of labor are distinguished by the socioeconomic mechanisms mediating underlying interdependences, notably organizations/institutions based on hierarchy or collective decision making (including the firm and family) on the one hand and spontaneous social processes (e.g., market processes) on the other.

Descriptions of the phenomenon date back to Plato and Xenophon. While all modern economists acknowledge the importance of division of labor as an elementary condition of productivity, much of mainstream economics treated it as a commonplace *external* to the theory. By contrast, Adam Smith emphasizes division of labor as the core of an *endogenous* process. Contributors to the analysis of division of labor include Charles Babbage and Karl Marx in the nineteenth and Allyn Young in the twentieth century, who provided the foundations for modern developments since the 1980s.

Foundational Core or External Commonplace?

Division of labor involves the decomposition of processes of (re)production, wealth creation, and knowledge development into separate tasks, each of which is performed by an individual or collective agent: a person, a class of persons, a region, a nation, an organization, or an institution. T. Hodgskin (1827 [1966]), J.J. Bachofen (1861), F. Engels (1884[1958]), and K. Marx were among the first writers emphasizing division of labor between the sexes. In particular, Engels draws on Bachofen's writings pertinent to the development of institutions governing behavior in the reproductive sphere (including an evolutionary sequence from primitive communism to matriarchal and finally patriarchal rule systems) in order to establish a 'materialist' theory of reproduction-related functional differentiation. Within this current of theorizing, power-related issues loom large, dealing with the way in which the division of labor is accompanied by systematic inequalities in the distribution of power and wealth. 'Fragmentation of knowledge' (an expression coined by Friedrich von Hayek) is a phenomenon closely related to division of labor. Regarding the evolution of scientific knowledge, the emergence of the disciplinary structure of modern science is a manifestation of division of labor, which is accompanied by other forms of specialization in methods and differentiation regarding levels of analysis. The shifting emphasis on issues and concepts throughout the history of ideas is sometimes regarded as a kind of *intertemporal division of labor*.

Division of labor is an old concept: in Western thought, classical antiquity produced remarkable descriptions of the phenomenon, including the explanation of some of the advantages of the division of labor within the organization of social production. In Plato's *Republic* (380 BC) division of labor is moreover discussed in its relations to accompanying phenomena such as exchange, markets, and money. In a tract entitled *The Education of Cyros*, Xenophon, a further writer of the fourth century BC, provides some additional insights, focusing the interdependence between division of labor, the development of greater cities, and concomitant demand-driven specialization of skills.

Division of labor is a complex concept: its theorization in economics establishes links between division of labor and other important concepts capturing various forms of economic dynamism, such as capital accumulation, growth, specialization, dynamically increasing returns to scale, complementarity, exchange, and indivisibility. The identity of human *individuals* as agents of division of labor is the basis for specific indivisibilities (e.g., related to the time necessary for learning specialized skills). Division of labor is moreover related to a range of broader socioeconomic issues such as inequality, heterogeneity, discrimination, alienation, power, cooperation, freedom, and social cohesion. Pertinent themes are in particular dealt with by currents of sociology and by Marxian Political Economy. The role of division of labor among the forces of social cohesion is an issue of pivotal importance in Émile Durkheim's evolutionary account of *Division of Labor in Society*: organic solidarity based on mutual dependence between individuals with different specializations is gradually superseding the traditional form of mechanical solidarity based on social homogeneity. Some of Durkheim's distinctions allow for grasping further aspects of division of labor as a complex concept: division of labor is not only intricately related to the dynamism of modern societies, but also to their endogenous crises. Referring to pathological tendencies of disintegration accompanying modern specialization processes, he distinguishes between anomic and rule-based division of labor. Moreover, he distinguishes between spontaneous and forced division of labor and between horizontal and vertical division of labor. In twentieth century sociology, the horizontal–vertical distinction reappears in the context of theories of social differentiation developed by authors such as Talcott Parsons and Niklas Luhman. Theories of social differentiation bring to the fore further dimensions of differentiation, including spatial differentiation, center periphery differentiation, and functional differentiation related to subsystems. Obviously, there exist parallels to some of the phenomena covered by economic

analysis. Moreover, pertinent currents of thought both in economics and in sociology invoke process-related properties of those phenomena and stress the importance of dynamic or evolutionary reasoning. Beyond those commonalities appearing at a prima facie level, analyzing the ways in which pertinent reasonings and theorizations in economics and sociology may be related to each other is a difficult task – reaching much beyond the scope of the present contribution. Anyway, the dynamism of economic specialization modeled along the lines of cumulative causation (which are widely regarded as a main explanation of the historically *unprecedented economic growth* of the past 250 years) somehow seem to find a parallel in sociological theories of differentiation processes (which are seen as related to the *increasing complexity* of modern society).

In political economy, different *types of division of labor* are primarily distinguished by the institutional mechanisms mediating the underlying interdependencies. There are two main classes of such mechanisms: (1) *Decentralized* and spontaneous social mechanisms, including markets as the paradigmatic case covering division of labor within the national economy as well as the international/global economy (world trade). (2) *Centralized* decision-making mechanisms, notably firms and other hierarchies. The second type of division of labor became visible and was conceptualized in the context of the development of the manufacturing processes accompanying proto-industrialization and industrialization: Adam Smith's pin factory and (in the twentieth century) F.W. Taylor's scientific management based on the analysis of workflows and their optimized recombination ('Taylorism') became prototypical models of intrafirm division of labor.

While almost all economists readily acknowledge the importance of division of labor as an elementary condition of productivity-enhancing technical change, in important strands of twentieth century economics it is confined to the role of a commonplace *external* to the theory, as Joseph Schumpeter put it. That is, the causes determining patterns of division of labor are regarded as *exogenous*. By contrast, Adam Smith's view of the subject is based on *endogenous* specialization processes, emphasizing the development of specialized skills among agents who in the beginning are very much alike.

How can we make sense of the vicissitudes of division of labor in the history of economic analysis? Here are some of the reasons for its ambivalent or even paradoxical status within the discipline of economics. First, the neglect of division of labor may have been caused by the fact that the mathematical tools supporting modern marginalist economics are specifically unsuitable for dealing with issues of specialization and division of labor. Second, the dynamic character of division of labor may be responsible for the vicissitudes and ambiguities characterizing its evolution within the history of economics when the latter was largely preoccupied with issues of static allocation theory and market equilibrium. Over and above all, the conceptual complexity of division of labor rendered it incongruous with the analytical ambitions of pure economics. In the wake of the programatic move toward *pure* economics advocated by leading protagonists of the neoclassical revolution, division of labor tended to be seen as a subject not really suitable for economic analysis in the proper sense, but rather for sociology on the one hand (regarding the social division of labor or social differentiation), or for studies in technology, engineering, and labor psychology on the other. Indeed, this view coincided with the rise of managerial analysis of firm-specific division of labor culminating in currents such as Taylorism.

Put in a nutshell, the disciplinary history can be summarized as follows: after a spectacular start as the pivotal element of socioeconomic progress in Adam Smith's Political Economy, division of labor retains a major role in the work of key figures of the nineteenth century of economics such as John Stuart Mill and Alfred Marshall, while Charles Babbage and Karl Marx significantly contributed to the further conceptual development. For much of the twentieth century, division of labor is a theme rather at the periphery than in or near the core of economics. The situation in sociology, however, was very different; in that discipline, the division of labor was a core concern throughout the twentieth century and into the present day.

Apart from a few incisive, but rather isolated articles on the subject (e.g., by Hendrik Houthakker, 1956) we find three somewhat more influential attempts to reintroduce division of labor as an important analytical concept of economics rather than an external commonplace. The first two are linked to the names of Allyn Young (1876–1929) and Nicholas Kaldor (1908–86). Both contributions are widely regarded as attempts commanding respect, but neither of them became the nucleus of a broader current of research gaining momentum as an important contribution to the understanding of economic dynamism. The last two decades of the twentieth century saw the development of the most recent of those three attempts aiming at reinvigorating the economic analysis of the division of labor: it includes models of economic geography and endogenous specialization in foreign trade proposed by Paul Krugman and others as well as the more general framework of the so-called New Classical inframarginal theory of specialization. The latter is supported by mathematical techniques suitable for considering specialization decisions (involving inframarginal comparisons between corner solutions rather than the usual comparisons at the margin) and concomitant interdependencies. To which extent those relatively new developments will change the general picture that emerged in the twentieth century ('division of labor as an external commonplace') is still an open question.

From William Petty to Adam Smith

After the forerunners in classical antiquity mentioned in the introduction, it was a key figure in the development of early modern economic thought who brought issues of division of labor to the fore in the seventeenth century: William Petty (1623–87). In his seminal *Political Arithmetick* (1671), he compares the advantages of the division of labor and specialization in various processes (textile manufacturing and sea transportation). In a tract published 10 years later, Petty (1683) touches upon the interdependence of specialization, the growth of cities and spacial concentration of certain types of activities. In the eighteenth century, writers from different backgrounds discussed various aspects of the division of labor: Bernard Mandeville (1670–1733) and Frances Hutcheson (1694–1746) became interested in socioeconomic questions in

the context of their broader concerns regarding the institutional and political implications of the emerging commercial society. While their focus was socioeconomic division of labor in a broader sense, writers such as Patrick Lindsay, Richard Campbell, and Joseph Harris dealt with division of labor in manufacturing illustrated by examples such as watchmaking (already used by Petty) and pin manufacturing, a showcase destined to make quite a career, as it was employed by the *French encyclopedia* and – most famously – by Adam Smith. Sir Josiah Tucker, Henry Martin, and Henry Maxwell made explicit the role of population size (an issue already implicit in discussions pointing to the role of bigger cities), anticipating the role of market size to be emphasized by Smith as well as related arguments by Durkheim. Turgot discussed the socioeconomic division of labor, linking it to economic phenomena such as capital accumulation and inequality. Beccaria (1771) explained advantages of the division of labor regarding the development of skill and dexterity.

As is the case with some other eighteenth century authors just mentioned (notably Turgot and Beccaria), division of labor is introduced in Smith's *Wealth of Nations* on the very first pages: for Smith, division of labor is close to the pivotal starting point of socioeconomic development. The starting point is exchange. According to Smith, exchange is related to basic properties of humans as communicating, social beings who by their nature very much depend on the assistance of others. The very "slow and gradual" development of division of labor is explained as the unintended effect of a concomitant "propensity in human nature" to "truck, barter and exchange one thing for another" (Wealth of Nations I. ii.1).

Authorities such as Edwin Cannan (1929: p. 96) suggest that Smith's analysis is remarkable for the emphasis put on division of labor, rather than for its originality or analytical depth. Joseph Schumpeter (1954: p. 187) claims that "nobody … ever thought of putting such a burden upon division of labor. With A. Smith, it is practically the only factor determining economic progress." This is clearly not meant to represent a mark of ingenuity. A careful reading shows that Smith's conceptual innovations are more important than suggested by such statements. First, it is hardly possible to overemphasize the thoroughly *dynamic* character of Smith's theory: division of labor is visualized as a process entailing cumulative causation. Second, it is portrayed as a *pervasive* phenomenon in the development of modern societies, including areas such as military defense, science and science-based technology, or law enforcement. Third, division of labor is perhaps Smith's most important case of a dynamic phenomenon emerging as the *unintended consequence* of human action. This foundational idea is closely related to Smith's view of exchange and markets as social mechanisms mediating progress based on human action, but not on the wisdom of human design. Unintended and cumulative effects do not only occur regarding market-mediated division of labor at the societal level (which is limited by the extent of the market, as Smith famously states), but also in the case of intrafirm division of labor: it is accompanied by cumulative advantages related to improvements in skill, dexterity, and judgment, and enhanced possibilities of mechanization.

Moreover, some unintended social consequences may trigger pernicious effects on the social and political life of modern societies. Those challenges are a recurrent theme in the pertinent literature: Marx related division of labor to a process of alienation accompanying capitalist dynamism, and Harry Braverman (1974) analyzed the degradation of work in the twentieth century. Undesirable social consequences of division of labor were also discussed by thinkers of Scottish Enlightenment, such as Smith's patron Lord Kames and Adam Ferguson (1767[1782]), who emphasized the tension between division of labor and the demands of republican citizenship. In Smith's view, decomposing labor processes into very small bits tends to make workers one-sided and even stupid. Worst of all, the development of simple industrial tasks that can be easily performed by children is a major problem as it hinders their education. The repetitive execution of those tasks does not make them fit for life in a modern society, including the defense of the nation.

Between Marx and Marshall: Developments in the Nineteenth Century

The conceptual history of division of labor in the nineteenth century is inextricably linked to a few names. Karl Marx (1818–83) is perhaps the author of the most comprehensive account of division of labor. In Marx's theory, division of labor is one of the three 'social forces of production' (along with 'cooperation' and 'science') whose development sets the stage for the restless productivity-enhancing change, which has become the key feature of modern economies. Marx also clearly distinguished between social division of labor and intrafirm division of labor in manufacturing: as Nathan Rosenberg emphasized, Marx studied the technological aspects of division of labor and their evolution with particular care. In Marx's theory, technological aspects of intrafirm division of labor were integrated in a more encompassing (if sketchy) analytical framework, thereby relating it to the development process of capitalist market economies at large. Before Marx, three writers stand out for having contributed to the economics of division of labor: Andrew Ure (1778–1857), Charles Babbage (1791–1871), and John Rae (1796–1872). Babbage and Ure were among the authors who were studied in great depth by Marx.

Rae (1834[1964]) emphasizes in particular the savings in the use of tools occasioned by division of labor. (Incidentally, he is also the author of the most important biography of Adam Smith in the nineteenth century.) Babbage develops a comprehensive theoretical vision of division of labor including processes of control and information in their relation to the overall industrial dynamism and he delivers a more detailed analysis of the advantages of division of labor. In particular, the mechanisms by which division of labor allows for saving of time and other kinds of costs are analyzed. They include (1) saving of time and other costs (such as waste of material) by more efficient *learning processes* triggered by the development of more specialized skill profiles; (2) the impact of specialization on dexterity; and (3) on the development and introduction of new machinery. Babbage (1832[1963]: p. 175) moreover makes a subtle point which was not entirely new, but is explained by him in a crisp and clear-cut fashion: "by dividing the work into different processes of skill and force" an employer "can purchase exactly that precise quantity of both

which is necessary for each process". If, by contrast, the whole work is performed by one worker, she must be endowed with sufficient skill to do the most difficult task and sufficient strength to execute the most laborious task. According to Babbage, the establishment of large factories can be explained by their potential for pertinent optimization of production processes. Analogous reasoning is also applied to the division of mental labor, illustrated by the production of logarithmic tables organized by Gaspard de Prony (1755–1839), who incidentally had read the chapter of the *Wealth of Nation* in which the organization of the pin factory is explained.

Andrew Ure (1835[1967]) highlighted aspects, which should become particularly important for Karl Marx: a tendency of division of labor toward deskilling of labor. Specific skills of laborers (imagine handicraft production) are substituted by machines based on scientific and technological knowledge and rational management. Skills are transferred from the workers to the machinery – with far-reaching implications for the locus of control. Along such lines of reasoning, Braverman's (1974) analysis emphasizes the distinction between social division of labor (which tends to enrich the human species *and individual agents*) and intrafirm division of labor into ever-smaller subprocesses (which is in tension with human needs and capabilities and hence tends to alienate the individual from the potential of the species).

Alfred Marshall's canonical textbook (1890: esp. chapters 8–12) provides a substantial amount of valuable reasoning regarding the economic implication of division of labor in a post-Smithian tradition. Yet this part of his work was not the one which carried the day as the Marshallian tradition in neoclassical economics of the twentieth century: in the successful Marshallian partial equilibrium supply-and-demand models with representative firms and consumers (allowing for invaluable advantages such as expedient diagrammatical teaching tools and mathematical modeling) division of labor plays little (if any) role.

The Twentieth Century: Young, Inframarginal Analysis, and the Household

Allyn Young's (1876–1929) paper (1928) is the outstanding, if somewhat isolated contribution to the analysis of specialization and division of labor in the first half of the twentieth century. Yet his work is frequently cited by the theorists who in the last decades of the twentieth century advanced formal models of specialization and division of labor including Xiaokai Yang and Sherwin Rosen (1983: p. 44), who called it "the zenith of the analysis of the connection between specialization and economic development." Young's concept of 'social increasing returns' is directly related to specialization and division of labor, foreshadowing the modern ideas of network theories related to division of labor. In Young's view, Smith's observation that division of labor is limited by the extent of the market should be understood in a more general way: on the one hand, it is also true that the extent of the market depends on the division of labor and specialization; the more specialized individuals are, the less able will they be to produce all the goods meeting their needs and wants themselves, and the more inclined will they be to buy some goods on the market. Concomitantly, the extent of the market is not only determined by the number of individuals in the market, but also by their purchasing power, which in turn reflects productivity, which again depends on division of labor. Taken together, a logic of circular and cumulative causation emerges, which is aptly summarized in Young's statement according to which division of labor is caused by division of labor.

Hendrik Houthakker's (1956) contribution is remarkable for its outline of a model capturing Smith's idea of endogenous specialization. Smith's emphasis on the extent of the market is the starting point for analyzing the role of transportation costs and – more generally – various types of transaction costs. Some contributions by Paul Krugman (e.g., 1980) on international trade belong to this strand of thought, implying a major advance toward modeling the idea of endogenous comparative advantage in trade: those models explain why trade may be beneficial even if countries are ex ante identical and shed light on trade patterns between industrialized countries.

In a number of contributions from the 1960s and 1970s, Nicholas Kaldor made use of Young's insights. In a volume entitled "Strategic Factors in Economic Development" (1967), he invokes the cumulative dynamism linking development of manufacturing to growth in labor productivity mediated by division of labor-driven increasing returns à la Young. In some programatic articles, Kaldor (e.g., 1972) criticizes the inability of mainstream economics to accommodate this kind of analysis, leading to 'irrelevance of equilibrium economics'.

In the late 1970s and 1980s, Sherwin Rosen (e.g., 1978) attempted to reinvigorate Young's 'social increasing returns', inter alia by introducing the concept of superadditivity, while James Buchanan introduced the closely related concept of 'generalized increasing returns'. A major attempt to bring in division of labor back from the cold is due to Xiakao Yang, who is the author of numerous articles with several coauthors in the 1990s and early 2000s. Yang and Ng (1993) summarize the reinvigoration of the economics of division of labor by the label *New Classical Economics* or *Smithian framework*. Its theoretical core are 'inframarginal' decisions regarding *what* activities to engage in. This is modeled by Yang and his coauthors on the basis of mathematical techniques such as (non)linear and dynamic programing and control theory allowing for corner solutions. Put another way: while traditional economics focuses *marginal* choices regarding resource allocation, i.e., choosing the quantity of resources devoted to each activity, given that the basic activity pattern is already determined, in a Smithian framework *inframarginal* choices regarding the nature and level of specialization are analyzed. As one individual's inframarginal choices determine her exchange patterns with others, all individuals' specialization decisions jointly bring about the social division of labor and determine the extent of the exchange network.

This current of research allows for a number of interesting applications, including international trade, the theory of the firm and urban economics (cf the review by Cheng and Yang, 2004). Those successes (including the demonstration that pertinent ideas by Smith, Young, and others can be developed in formal frameworks) notwithstanding, the claim that it shifted division of labor from the periphery to the core of economic analysis would be an exaggeration as yet.

A different current of contemporary research focuses division of labor in the sphere of reproduction. Stimulated by Gary Becker's explanation of the division of labor in the household as the outcome of mutually beneficial exchange between husbands and wives (driven by natural comparative advantage), various strands of theorizing stress the role of asymmetries of power, status, and wealth. Cooperative game theory widens the horizon of economic models by making explicit the role of bargaining power in intrafamily decision processes regarding labor market participation and the allocation of household work. In the sociological literature, the role of gender display models/gender ideologies is brought to the fore (see Brines, 1994; Greenstein, 2000) in order to explain sticky asymmetries, such as the fact that women still do the majority of household work, despite dramatic increases in labor force participation of married women.

Abstract

High levels of divorce in the United States are both persistent and unusual from an international perspective. In recent years, divorce has become more stratified, with marital dissolution declining for the most educated while it remains high for those without a college degree. Generally, divorce is associated with declines in the well-being of adults and children, although divorce is not universally associated with poor outcomes, suggesting that social context matters. That divorce is increasingly concentrated in the most disadvantaged groups and sometimes has negative consequences for adults and children, suggests that it both reflects and further contributes to stratification in the United States.

Divorce Levels and Trends

Overall, in the United States, about half of American marriages will end through divorce or separation, although the risk of dissolution varies considerably by social context (Cherlin, 2010; Raley and Bumpass, 2003). While divorce rates increased rapidly in the 1960s and 1970s, this was merely an acceleration of longer term trends in divorce that had been occurring since before the twentieth century (Glick, 1986; Martin and Bumpass, 1989). Beginning in the 1980s, unadjusted divorce rates tipped slightly downward, and recently most researchers have argued that the probability of divorce has either continued to decline or essentially stabilized. However, the deterioration in data sources for divorce statistics, coupled with a common failure to account for compositional changes in the married population across time, may have worked to disguise an actual increase in the divorce rate in recent years (Kennedy and Ruggles, 2013).

Divorce rates in the United States have long been elevated in comparison to those of other nations. Most European countries see between 20 and 30% of their marriages dissolve within 15 years, compared to the United States average of 42% (Andersson, 2003). Lower levels of union dissolution are often observable in both Southern and Eastern European Catholic nations. Italy, Spain, Slovenia, and Poland all with fewer than 10% of marriages dissolving within 15 years (Andersson, 2003). European divorce rates have also been increasing in recent decades, so although the United States continues to have the highest among developed nations, the gap appears to be narrowing (Amato and James, 2010).

When divorce is studied cross-nationally, especially among developed nations, it is helpful to consider cohabiting unions that break up to understand the full picture of union stability. Scandinavian countries in particular are known for having low rates of marriage (and consequently low rates of divorce), but high rates of long-term cohabitation. When cohabiting unions are taken into account, some European countries (e.g., Sweden) have relationship dissolution rates that approach the rates in the United States (Andersson, 2003; Popenoe, 2005).

Correlates of Divorce

Socioeconomic Status

Early theorists (Becker, 1981; Parsons, 1949) attempted to explain rises in divorce as a consequence of women's entrance into the paid workforce. Becker (1981), for example, argued that many of the gains to marriage were realized through specialization. Others suggested that increased earnings lowered the barriers to leaving unhappy marriages (Ross and Sawhill, 1975). These early theories, often referred to collectively as the Women's Economic Independence explanation, were supported by research showing that the historical rise in divorce rates tightly corresponds to increases in women's labor force participation and earnings (Ruggles, 1997). Yet, studies examining these associations at the individual level have produced far less convincing support. Some research finds a positive association between women's own earnings and her risk of divorce (e.g., Ross and Sawhill, 1975) but some finds a curvilinear relationship, no association, or a negative one (e.g., Rogers, 2004; Greenstein, 1990; Hoffman and Duncan, 1995). Even among analyses using similar measurement approaches (e.g., the ratio of wives income to total family income), some find support for Economic Independence theory while others do not (Sayer and Bianchi, 2000).

Inconsistencies in findings might stem from the control variables included in the statistical models (Sayer and Bianchi, 2000), whether the analysis distinguishes work hours from wage rates (Teachman, 2010), or whether the modifying influences of context are considered (Schoen et al., 2006; Cooke and Baxter, 2010). This suggests that women's participation in the paid labor force is connected to marital stability through multiple pathways some of which help to stabilize marriage (e.g., by increasing family resources) and others that can undermine it (e.g., stress and long work hours creating more work–family conflict). The gender role attitudes of the couple, their marital happiness, as well as the broader institutional context can shape which of these pathways dominates the association. Perhaps the most important pathway runs from marital stability to female labor supply, as a recent review suggests (Ozcan and Breen, 2012; see also Oppenheimer, 1997; Rogers, 1999).

In contrast to earnings, women's educational attainment is consistently negatively associated with the risk of divorce, at least in the United States. More specifically, having a college degree is associated with a lower risk of divorce, but women with some college have a higher risk of marital instability than those who have just a high school degree, a finding referred to as the 'Glick effect' (Glick, 1957). Over time, educational differentials in divorce have grown as divorce rates to college educated women declined after 1980, while they remained steady or continued to climb for those with lower levels of education (Martin, 2006; Raley and Bumpass, 2003). Interestingly, education is not associated with risk of divorce in all countries and the association may even be negative in some contexts, suggesting the importance of institutional contexts for socioeconomic disparities in family stability (Härkönen and Dronkers, 2006; Cooke and Baxter, 2010).

Premarital Cohabitation

The slight decline and subsequent stabilization of the divorce rate have been accompanied by rapid increases in cohabitation rates. Conventional wisdom often held that cohabitation could function as a way to guard against future divorce by testing couples' compatibility and the relationship's durability through shared living (Rhoades et al., 2009). In contrast, multiple studies over time consistently found that premarital cohabitation was associated with lower marital quality and an increased divorce risk (Axinn and Thornton, 1992; Kline et al., 2004; Stanley et al., 2010; Jose et al., 2010). Researchers have proposed two main explanations for the association between cohabitation and divorce. First, those who select cohabitation over direct marriage may possess certain characteristics that place them at a greater risk of divorce, like poor relational skills or nontraditional views of divorce and marriage (Phillips and Sweeney, 2005). Research also supports the idea that there is something endogenous to the experience of cohabitation that can both foster lower commitment between partners, and can prolong weaker relationships that would not have otherwise become marriages (Axinn and Barber, 1997; Stanley et al., 2006). But there is evidence that the relationship between premarital cohabitation and divorce may be weakening if not absent in recent marriage cohorts (Reinhold, 2010; Manning and Cohen, 2012). It may be the case that the diffusion of cohabitation across populations has worked to mitigate the selection factors that tied cohabitation to divorce.

Race–Ethnic Differences

Blacks and US-born Mexicans have higher rates of divorce than non-Hispanic Whites (Phillips and Sweeney, 2005). Age at marriage, educational attainment, premarital fertility, as well as premarital cohabitation contribute to these differences (Phillips and Sweeney, 2006). Couples marrying in their teen ages and early 20s face a higher risk of dissolution (Raley and Bumpass, 2003) and this, along with lower levels of education, accounts for some of the higher risk of marital dissolution among US-born Mexican women (Phillips and Sweeney, 2006). Blacks marry at later ages than Whites or Hispanics, so age at marriage cannot explain higher levels of divorce among African-Americans. Nonetheless, lower levels of educational attainment combined with more premarital fertility and premarital cohabitation account for some, but not all, of the higher risks of divorce for blacks (Phillips and Sweeney, 2006).

Additional Correlates

Divorce in the family of origin has also been linked to children's risk of divorce in their own marriages (Amato and DeBoer, 2001; Amato and Cheadle, 2005; Wolfinger, 2005). Children may observe and internalize ineffective patterns of communication and conflict resolution between parents and subsequently carry poor relationship skills into their future marriages (Caspi and Elder, 1988; Amato, 1996). Alternatively, when children experience a parental divorce their overall commitment to marriage may weaken by seeing the fragility of the marital contract (Amato and DeBoer, 2001). Some contend that the intergenerational transmission of divorce has weakened over time, but this trend remains contested (Li and Wu, 2008; Wolfinger, 2011).

Certain orienting beliefs and values may also work to either protect or undermine partners' marital success. Gender ideology can provide couples with core assumptions regarding roles in the marriage, and usually has implications for the balance of power between spouses. The direct effect of holding egalitarian vs more traditional attitudes toward marriage is rarely studied in isolation, but there is some evidence that women with egalitarian attitudes are more likely to divorce than women with more traditional views of household and family life (Kaufman, 2000). It is more likely though, that gender role beliefs influence marital stability by moderating how couples negotiate different decisions, such as the division of paid and unpaid labor (Cooke, 2006). Ultimately what may be important is how 'her' and 'his' gender role attitudes fit together (or fail to do so); the combination of an egalitarian wife with a more traditionalist husband is associated with the highest risk of marital instability (Clarkwest, 2010). Religious beliefs may work to influence couples' beliefs about marriage, and can help embed couples in supportive social networks of their religious communities (Call and Heaton, 1997; Lehrer, 2004). However, identifying with a religious belief does not protect couples uniformly. Couples that hold dissimilar religious beliefs are at an increased risk to experience a divorce (Lichter and Carmalt, 2009; Vaaler et al., 2009).

Consequences of Divorce

The dissolution of a marriage has implications for the well-being of the spouses that are involved, as well as any dependents they may have. The study of the consequences of divorce has commonly considered socioeconomic, health, and emotional–behavioral outcomes of men, women, and children. Generally, sharing a household is more economical than living separately and couples who divorce lose this advantage. Because children typically live with their mothers following divorce and women usually have lower incomes than the men they are married to; women and children often experience steeper declines in economic well-being than men. Past research has estimated that wives experience a 27% decrease in their standard of living after divorce, while husbands may

experience on average a 10% increase (Peterson, 1996). These estimates are not nearly as drastic as those published in the 1980s (Weitzman, 1985) and it is possible that declines in standard of living are due to factors other than divorce itself (Smock et al., 1999). Moreover, as women's investments in paid employment have increased, the negative economic consequence of divorce for women and children may have declined (McKeever and Wolfinger, 2001) but it has not disappeared (Osborne et al., 2012). Altogether, the evidence suggests that divorce results in declines in economic well-being for women and children. It is associated with other declines in well-being as well.

Divorce is associated with declines in health, although the patterns vary by gender and health outcome. Divorce is associated with short-term declines in physical health for men, but not women (Williams and Umberson, 2004; Hewitt and Turell, 2011). Women, however, experience declines in mental health, especially when they have young children (Williams and Dunne-Bryant, 2006). The longer term health consequences of divorce, however, are less well established, at least in part because it is difficult to separate the effects of divorce per se from factors that cause divorce. Since the rise in divorces in the past half century a growing number and proportion of children have experienced a parental divorce during their lifetime. Children with divorced parents score lower on a number of well-being measures when compared to children with continuously married parents. For example, children whose parents divorce are less likely to graduate high school (Pong and Ju, 2000) and more likely to have a teen birth (Wu, 1996). Some of this is likely a consequence of the poorer economic resources of children living with single parents, but some may also be due to the stress and disruption caused by changes in household structure (McLanahan and Sandefur, 1994; Cavanagh and Huston, 2006). Some of the poorer outcomes of children whose parents divorce are due to factors, like maternal mental health, that select families into divorce rather than to the consequences of family instability (Fomby and Cherlin, 2007).

Despite substantial research on this topic, there is continued debate over whether divorce is better understood as a discrete crisis or a chronic strain for the individuals involved and the consequences of divorce for children's well-being are still debated. This is partly because of the complexity of the question and the fact that aspects of the social context matter. For example, postdivorce adjustments can vary by whether the former marriage was high conflict or low conflict (Amato, 2010). Nonetheless, analyses using state-of-the-art analytical approaches often find parental divorce associated with at least some poorer outcomes for children in some situations, suggesting that divorce does have harmful consequences for some children.

Conclusion

Although divorce rates have been roughly stable over recent decades, some of this stability has been achieved through a later age at marriage and a higher proportions of women, especially economically disadvantaged women, never marrying (Goldstein and Kenney, 2001). Even so, marital instability today is much more common among those with the fewest economic resources. Although the harmful consequences of divorce for the well-being of adults and children may not be as great as they once were, the concentration of family instability in populations with the fewest economic resources may contribute to increases in social and economic inequality (McLanahan, 2004).

The growing rates of divorce in European countries also suggest there is variation in how different factors associated with divorce may be more or less predictive when operating in different contexts. In a comparison of American and European divorce research, Amato and James (2010) note that European findings typically support the relationships between risk factors and divorce that have been identified in the United States. When certain predictors, like high levels of education fail to be as consistently protective in European countries, it may reflect unequal levels of marriage deinstitutionalization, government welfare policies, and heterogeneity in societal stratification across countries (Härkönen and Dronkers, 2006).

Abstract

This article outlines key ideas and issues in the complex field of doctoral education as represented in the English-speaking literature. After referencing its brief history, range of fields in which it is researched, and the breadth of research foci, attention is given to one field – learning/development/pedagogy. Explored are epistemological approaches, changes occurring in focus and emphasis, research trends and issues, ending with methodological directions and issues. A key thread is the difficulty of understanding doctoral education since, like many other educational undertakings, it is very much influenced by context.

Introduction

A starting point in attempting to depict doctoral education internationally is acknowledging that any representation will leave out much and will represent a viewpoint from a particular space in time, geographical location and life journey. In this instance, my viewpoint is colored by my age and gender: 60s female; my ethnicity and nationality: white Canadian; my scholarly interests: researcher-doctoral-academic learning and development; my working environment: the UK, North America, and Europe. In this article, I outline key ideas and issues in the complex field of doctoral education as represented in the English-speaking literature. Initially, I reference its brief history, range of fields in which it is researched, and the breadth of research foci. Then I explore one field, doctoral learning/development/pedagogy, since it is the area in which I principally locate myself. I elaborate epistemological approaches, changes occurring in focus and emphasis, research trends and issues, ending with methodological directions and issues. A key thread that runs through this essay is the difficulty of understanding doctoral education since, like many other educational undertakings, it is very much influenced by context: broadly social, cultural, and economic influences, and more specifically national histories of doctoral education as well as national, provincial/state, and institutional policies. (I refer throughout to doctoral education rather then PhD education to be inclusive of the growth of other kinds of degrees, for example, EdD and DPsych; however, the focus of my discussion is largely the PhD since it is the most common and researched degree.)

Current Knowledge

While the origins of the doctorate are in the 1800s – first in Germany and then the USA – doctoral education as a field of inquiry is relatively new, in fact, was little examined until the 1980s. (Examples of still cited publications in the 1990s include Cullen et al. (1994) in Australia and Delamont et al. (1998) in the UK.) During the past quarter century, research in this area has grown enormously in visibility, as regards policy, institutional visibility, and research. In relation to policy, initiatives such as the European Bologna Agreement designed to enhance academic mobility have focused national attention in European countries on the structure and length of programs. In countries such as the UK and Australia, attention is directed at doctoral education due to national quality assurance agencies which review institutions on a regular basis as to their incorporation of doctoral Codes of Practice. And in places without national policy or national accountability requirements, for instance the USA, there have been initiatives by nongovernmental agencies such as the Carnegie Initiative on the Doctorate (Golde and Walker, 2006) to engage departments in evaluating and changing their doctoral practices. More recently in a range of countries, national funding councils have generated funding policies for students that have led to the creation of innovative structures (e.g., called variously doctoral training centers/networks, doctoral schools) which may, for example, highlight interdisciplinarity or industry linkages. For an interesting analysis of international changes in doctoral education, see Nerad and Trzyna (2008).

As a way of situating the growing and broad English-speaking literature on doctoral education, a brief search of abstracts (doctoral and PhD education) in the USA and the UK showed the number of publications at least tripled from 1990–2000 to 2000–12 and included contributions from non-English-speaking countries such as (in alphabetical order) China, France, Japan Korea, the Netherlands, the Nordic/Baltic countries, Pakistan, and Spain. As interesting perhaps is the range of fields/journals in which these papers were published, demonstrating that interest is widespread: art and design, anatomy, counseling, dentistry, ecology, education, engineering, finance and accounting, geography, medicine, nursing, pharmacology, psychology, and theology. The focus of these studies was also diverse, for instance: assessment; evaluation and accountability; career preparation, curriculum and programs; diversity; international students; internationalization; kinds of doctorates (practice- and industry-based, professional, and by publication), management; the nature and purpose of the doctorate; policy development; research and other training; and supervision. As can be seen in this range of foci, studies often explore individual experience; institutional policies and practices; and less frequently national policies, and social and economic contexts; and international competitiveness.

One of the difficulties of this area of inquiry is that differences are rarely noted, though there are sometimes quite

distinct contrasts across national boundaries (as well as across and within institutions) as regards the structure, form, and terminology related to doctoral education; as well as the career structures and potential job markets that exist e.g. in North America, dissertation refers to doctoral education; in the UK, to Master's education.

Intellectual Background: Prevailing and Emerging Schools of Thought

As is apparent from the broad number of fields in which doctoral education is researched, studies draw on a range of epistemologies and methodologies and are published in different journals. Unfortunately, these different scholarly networks rarely meet despite their common interest in doctoral education. In other words, studies within each network tend to take up only the issues pertinent to their communities. One field of inquiry is academic communication with a hermeneutic approach more prominent (understanding writing as a process, multiple academic genres to learn) (e.g., Kamler and Thomson, 2006). Another area of research is the sciences using largely empirical pragmatic studies documenting issues related to producing researchers/scientists (lack of career opportunities for graduates, problems in learning research practices); these studies tend to be published in science journals. The final grouping is learning/development/pedagogy using a range of methods and epistemologies in higher education journals (supervision, assessment, and accountability).

Given this range, I will in the remainder of this review focus on only the last area, learning/development/pedagogy. In this literature, there are differences in the prevailing conceptual frameworks used. For instance, in the USA, a socialization framework underpins many studies though not always fully elaborated. This framework, originally developed by Tinto for undergraduate education, conceptualizes doctoral education using a three-stage model in relation to institutional doctoral persistence (Weidman et al., 2001). From this perspective, individuals are inculcated into the normative knowledge and practices of the field. In contrast, in the UK and to some extent Australia, a more critical post-structuralist stance is prevalent drawing often on Bourdieu's body of anthropological–sociological work (e.g., Bourdieu, 1977). These studies often present individuals as strongly influenced by the structural elements of academic work, often in negative ways. What both these approaches share in common is a privileging of structure over agency. While a structural or systemic perspective is necessary to understand the influence of factors beyond individuals' control, personal agency needs to be incorporated for a realistic representation of doctoral experience, that is, that individuals while experiencing difficulties can often navigate different structural elements to advance their intentions. Recently, such work has begun to develop, often based on Archer's (2000) philosophical work (e.g., Clegg, 2008). As well, there is an emerging interest in cultural–historical activity theory (e.g., Engestrom, 2001) of which later representations incorporate a focus on relational agency (e.g., Bowen and Roth, 2007). These shifts to include attention to individual agency echo, I believe, those occurring in other social sciences fields (King, 2010).

Changes in Focus or Emphasis Over Time: The Influence of Policy

Changes in research focus reflect changing policy emphases. For instance, national initiatives to attract more international students and demonstrate greater student diversity have led to more research on the experiences of these individuals. Calls to better prepare doctoral students for nonacademic careers have lead to more attention on the design and evaluation of a range of training opportunities beyond research training, for example, communication skills and teamwork. The shift in funding council policies related to student funding, for instance, in the UK and Australia, has led to more study of doctoral programs that integrate links to business and industry, or inter/transdisciplinary work (often within doctoral centers referred to earlier).

Current and Emerging Directions and Issues in Research

The field lacks a comprehensive and critical literature review. The only extant review (Leonard et al., 2006) examined 120 UK publications; the distribution of foci was about a third each of pedagogy (the majority supervision); peer support; and outcomes (e.g., completion times and rates, and employment patterns) with the remainder being the viva (oral defence in North America) and other forms of assessment. The gaps noted that are still true today internationally include:

- a lack of studies outside education and the social sciences more generally;
- little attention to mode of study (e.g., full time or part time, face-to-face, blended, or distance);
- few systematic comparisons across institutions;
- transition from higher education to work; this is still a gap and needs attention given the increasing scarcity of full-time permanent academic positions and the increase in post-PhD researcher positions (often contingent and short term).

Gaps noted that are less the case today include:

- details beyond gender were rarely considered; less true today given policy attention to attracting increasingly diverse students;
- the lack of discernible theoretical frameworks; I concur as regards the prevailing ones though newer approaches are often well argued perhaps because they are new;
- a very little research done on the students' perspective: less true today internationally, for instance, a number of recent studies have examined the role of student networks;
- a lack of quantitative studies; this was not the case outside the UK at that time and is less the case today in the UK though many of these studies lack a conceptual framework.

Other areas for inquiry that I believe deserve attention include: career preparation and transition, ethics education which to date focuses largely on ethical approval rather than ethical practices, studies of the new doctoral training structures, and international comparative studies given social and economic drivers internationally. Two broader issues bear attention: the integration of studies published in

languages other than English, and a critical review of the literature.

Methodological Issues and Problems

If one looks across the field, the majority of studies whether qualitative or quantitative, use a limited number of methods, mostly one-time surveys, and one-time interviews. Rarely does one see longitudinal studies, yet such studies, both qualitative and quantitative, could provide needed insights into transitions from the doctorate to other work, or what leads students to leave the doctorate. Further, nontraditional methods would offer other insights, for example, ethnography is rarely used yet captures interactions and practices that other methods do not.

Secondly, as noted earlier, doctoral education has been studied from a range of viewpoints (e.g., individual, institutional, national, and international) and different perspectives (e.g., learning, policy, finance, history, philosophy, and organizational behavior). This breadth demonstrates the complexity of the phenomenon. However, this complexity brings with it difficulties; integrating the different viewpoints would provide a more robust understanding of doctoral education, yet this is extremely difficult.

Conclusions

Doctoral education is a growing and relatively robust area of inquiry, but as in most fields of research there are substantive issues, including methodological challenges. Moreover, my view is that we need to rethink the scope of what we, as researchers, consider the boundaries of our interest. I have already mentioned the need to address post-PhD transitions. More important, I believe, is a necessary reframing given the increasing requirement for completion within 3–4 years in contrast with 5–8 years previously. This legislated change does not take account of the actual time that it takes to develop the range of abilities and qualifications expected of an independent researcher. Thus, aspects of doctoral learning and development have been moved to the post-PhD period with a subsequent increase in the number of post-PhD researcher positions in which individuals attempt to develop the portfolios they need to be competitive if they wish an academic career. It is for this reason that I suggest we need to reframe the field of inquiry from doctoral to researcher education and include those post-PhD in our studies.

Doctor–Patient Interaction in the West: Psychosocial Aspects

Joshua D Meadors and Carolyn B Murray, University of California, Riverside, CA, USA

© 2015 Elsevier Ltd. All rights reserved.

This article is a revision of the previous edition article by J. Weinman, volume 6, pp. 3816–3821, © 2001, Elsevier Ltd.

Abstract

The present article draws from research literature to provide an overview of psychological and social aspects of doctor–patient interactions. First, doctor–patient communication itself is reviewed in terms of various approaches, processes, and methods of measurement. Next, the article discusses patient and physician characteristics and other antecedents that influence the doctor–patient relationship (e.g., gender and ethnicity). Outcomes related to the quality of doctor–patient communication are then discussed, with a focus on patient satisfaction and adherence to medical advice. The article concludes with an examination of interventions regarding doctor–patient communication, followed by a brief summary.

Introduction

The quality of health care a given patient receives largely depends on the quality of the interaction between the patient and the health care provider (e.g., physician). Doctor–patient communication (also called patient–provider communication, patient–practitioner communication, and other synonymous terms) generally refers to various aspects of the interaction between the care provider and the patient, including but not limited to the provider's bedside manner, either party's use of verbal and nonverbal communication, and the exchange and comprehension of medical information and advice. Communication plays a central role in these medical interactions, and psychological studies have consistently shown how this property of the doctor–patient relationship is related to medical outcomes. Likewise, common health care issues (e.g., patient adherence) are strongly influenced by the nature of the communication between the physician and patient.

The present article provides a brief review of the doctor–patient interaction and its psychosocial aspects. The doctor–patient interaction is discussed here in three sections: (1) a description of the doctor–patient interaction and related processes, (2) antecedents or other characteristics that influence the doctor–patient interaction, and (3) consequences or outcomes determined by the nature of this interaction. The article concludes with a discussion of interventions followed by a brief summary regarding research on doctor–patient interactions.

The Doctor–Patient Interaction

Previously, medical practice considered the patient in a primarily biomedical, evidence-based context, but suggestions for clinical methods that incorporate the patient's personal perspective gave rise to what is currently considered the patient-centered approach, which focuses on the entirety of the patient and how biological, psychological, and social factors are all related to what is considered physical health. Patient-centered communication has been distinguished from terms like 'patient-centered care' and 'patient-centeredness' (see Epstein et al., 2005), but the present article focuses on the general aspects rather than distinctions. In this context, patient-centered care typically involves features like effective verbal and nonverbal communication, expressive empathy, successful transmission of information, and encouragement of the patient's partnership and participation. Indeed, the patient-centered approach seems to result in more effective interactions and more positive medical outcomes than the biomedical or doctor-centered alternative (e.g., Roter and Hall, 1992). However, a more integrative approach has been to treat the doctor–patient relationship as an entity in and of itself, taking into account both the provider and the patient's attitudes, beliefs, values, and cultural backgrounds, as well as how these characteristics interact dynamically to produce a variety of medical outcomes. Typically, doctor–patient interactions are described according to three distinct approaches: doctor centered, patient centered, and relationship centered.

The doctor-centered approach is the older, more traditional approach in medicine. The physician tends to dominate the interaction with a focus on asking 'yes–no' medical questions generally related to the physiological pathologies of the patient. However, the doctor-centered approach tends to lack the patient's perspective, a sense of partnership, and an interpretation of psychological and social factors, which has led to the more modern patient-centered approach to medical practice. The two primary components of patient-centered care are that (1) the entirety of the patient should always be considered, including any relevant psychosocial information and (2) the patient is an active participant in the communication process, providing necessary psychosocial information and taking part in medical decisions. Over time, the predominant model for doctor–patient relationships has shifted from the paternalistic, doctor-centered approach to the more egalitarian, patient-centered approach. Although the patient-centered approach appears to stress psychosocial information in contrast to a more biomedical model, the term 'biopsychosocial' is often used to indicate the importance of balancing these sources of information. The doctor-centered versus patient-centered nature of the interaction is one of the most basic features of physician–patient communication; however, some critics argue that neither approach represents the entirety of the doctor–patient interaction itself (similar to how the doctor-centered approach does not represent the entirety of the patient).

The relationship-centered approach seeks to incorporate the knowledge, attitudes, and beliefs that come from the provider's perspective as well as the patient's, focusing on the relationship itself as an entity comprising and continuously influenced by the characteristics of both the patient and provider.

In Hall and Roter's (2007) review of doctor–patient interactions, the authors highlight five characteristics that exemplify the relationship-centered approach, namely, relationship-centered care must be medically functional, facilitative, responsive, informative, and participatory. In this sense, these are not responsibilities of only the physician or the patient; rather, they are responsibilities of the patient–provider relationship itself. The 'medically functional' aspect refers to the degree to which the doctor–patient relationship affects the quality or performance of basic medical procedures, such as scheduling the visit and using resources appropriately (i.e., in terms of managing the visit as well as the technical procedures used for diagnosis and treatment). The 'facilitative' aspect refers to the degree to which the relationship allows the patient to talk openly and completely about the illness and/or psychosocial distress in a manner that is well understood and considered by both parties. The 'responsive' aspect refers to the degree to which the patient's emotional concerns are met with supportive, empathic attempts to address these issues. The 'informative' aspect refers to the degree to which medical information and recommendations are shared in a manner that the patient understands and is motivated to use properly. The 'participatory' aspect refers to the degree to which patients are able and encouraged to play a significant role in the consultation process (e.g., in medical discussions and decision making) and to be generally responsible about their medical care.

Beyond more general distinctions of physician–patient interaction (e.g., problem-focused versus emotion-focused responses), a review of doctor–patient communication (Roter and Hall, 1992) indicates there are six categories of communication that occur between physicians and patients: information giving, information seeking, social conversation, positive talk, negative talk, and partnership building. Roter and Hall's (1992) examination of dialogue between patients and physicians also provides a statistical representation of the average frequencies of various types of talk that occur during the medical interaction. On average, 35% of physicians' talk involves information giving (e.g., providing medical information, counseling, and recommendations), 23% involves information seeking (e.g., asking closed-ended or open-ended questions), 6% involves social conversation (e.g., nonmedical or casual discussions), 15% involves positive talk (e.g., statements of approval or facilitative back channel responses like 'mm-hmm' and 'aha'), about 1% involves negative talk (e.g., disagreements, confrontations, or antagonism), and 11% involves partnership building (e.g., attempts to get a patient more involved and engaged in the medical interaction). On average, 47% of patients' talk involves information giving (e.g., answering the care provider's questions), 7% involves information seeking (i.e., asking questions), 13% involves social conversation, 19% involves positive talk, and 8% involves negative talk (e.g., disagreements and criticisms of the physician). Some of these frequencies can be explained by the tendency for physicians to talk more than patients, contributing to about 60% of the conversation. The average medical consultation lasts 20 min or less (although there is much variation), and up to half of this time can include periods of silence, interruptions, or activities that do not directly involve the patient. Physicians' reliance on closed-ended questions and medical counseling may be seen as a way to maximize the time spent during the medical encounter, but they may still be expressing negativity in a variety of indirect ways. Meanwhile, patients may feel obligated to answer the physician's questions and be too intimidated to ask questions of their own, but they tend to engage in more nonmedical conversation and can more freely and directly express their emotional involvement through positive and negative talk. By and large, patients are more likely to disclose health information when the physician discusses more psychosocial issues and displays a supportive, attentive nature.

The overall quality of the doctor–patient interaction can be assessed in a variety of ways. From a qualitative review of patient perspectives, the quality of the medical relationship depends on how long they have worked with the same doctor and how well their various interactions have proceeded (Ridd et al., 2009). This is further enhanced by an egalitarian approach that includes the patient and doctor's knowledge, understanding, trust, and liking of each other. More quantitative methods involve surveys and questionnaires that examine various dimensions of the doctor–patient relationship (e.g., trust empathy and relationship building). Researchers also employ the rating and measuring of behaviors, statements, and other communication aspects present in audio- and video-recorded doctor–patient interactions. Methods such as examining previously recorded doctor–patient interactions provide relevant insight into variables related to communication quality. For example, what appears to be a negative medical consultation may be explained by negative behaviors exhibited by the patient (e.g., in response to their preexisting illness) that are misdirected or misinterpreted but ultimately reciprocated by the care provider. Because of this, variables such as the doctor and patient's satisfaction with the medical visit are often positively correlated.

Antecedents of the Doctor–Patient Interaction

The doctor–patient interaction is a dynamic process involving a given patient and care provider; therefore, a number of factors influence this relationship. Something as simple as the time of day can determine how long the medical consultation lasts, with earlier visits lasting longer than average and later visits lasting shorter (Byrne and Long, 1976). At an individual level, patients differ in how much they want to be involved in the medical process, how much medical information they would like to receive, and what they expect the medical consultation to accomplish. Generally speaking, older patients, male patients, nonwhite patients, patients with lower incomes, and patients with lower levels of educational or occupational attainment tend to prefer or display more passive, dependent relationships with their care providers (e.g., Arora and McHorney, 2000). Patients also vary in how appropriate they believe it is to provide psychosocial information to their care provider, which happens to be a key component of the patient-centered and relationship-centered approaches. Basic

differences among physicians follow a similar pattern, with variation in how much and what type of information they believe the patient should receive, the role the patient should play in the consultation and decision-making processes (e.g., active or passive), and their focus on the physiological versus psychosocial nature of the information given to, provided by, or discussed with the patient. Several studies (e.g., Street et al., 2005) suggest that patient participation depends on a variety of factors, such as the clinical setting or the degree to which the physician adopts a patient-centered communication style, as well as the interaction between several personal and situational characteristics.

Both the patient and the provider have specific attitudes, beliefs, values, personalities, and cultural backgrounds, and these characteristics cannot be readily detached from the interaction at hand. For example, expectancy effects may occur as a result of the patient's cultural background and the physician's prior experience or beliefs regarding that cultural background, or a patient may ultimately receive better or worse medical care simply because of how much the physician likes that individual. The following sections detail characteristics of the patient and provider that may influence the medical interaction and its outcomes.

Gender

Gender and engendered differences in socialization practices influence the expression of a large number of personality characteristics, many of which are relevant to the quality of the doctor–patient interaction. For example, large gender differences in communication style have been consistently reported in previous literature (e.g., Hall, 1984/1990, 2006). Women generally exhibit better nonverbal communication skills; they tend to more accurately express and interpret emotional cues, and they also display more interpersonal warmth and engagement (e.g., smiling, eye contact, standing close, and touching). Men generally appear less emotionally concerned and tend to be more dominant in their interpersonal interactions. Although evidence of these gender differences is often taken from outside of clinical settings, Roter et al. (2002) review of the literature indicates that men and women also tend to show these behavioral differences in the clinical context, with implications for both patients and physicians. For example, nonverbal sensitivity may allow a physician to detect and address feelings or misgivings the patient may hesitate or be unable to convey verbally.

Male and female physicians typically provide the same amount of medical information, but female physicians often apply more psychosocial aspects to the discussion. Furthermore, women tend to ask more questions and encourage patient participation while also displaying more positive and/or emotional verbal and nonverbal behavior. They also tend to have longer visits, report liking their patients more, and more readily adopt a patient-centered, psychosocial approach to practicing medicine (Roter and Hall, 2004). Ultimately, patients respond to male and female practitioners differently due to these discrepancies in communication styles, engaging more with female physicians (e.g., by talking more, providing more information, or otherwise participating more in the interaction). However, even though female practitioners tend to exhibit arguably more desirable communication styles and report liking their patients more than male practitioners do, there seems to be no gender difference in the patients' liking of or satisfaction with their physicians.

Gender differences in communication styles also occur among patients, with women participating more during the interaction. However, this may also be based on expectations and responses from the care provider, as women tend to receive more opportunities to be involved in the interaction, and the information they receive tends to be presented in a more understandable manner. These differences are highlighted by studies that show patients participating the least when both the patient and physician are men (Kaplan et al., 1995). Despite this, there seems to be no gender difference indicating women are more satisfied with their health care interactions than men are.

Ethnicity, Culture, and Socioeconomic Status

The literature documenting ethnic disparities in health care is fairly extensive and consistent (e.g., Murray and Woods, 2009; Whitfield et al., 2012). Ethnic and class differences that occur in other societal institutions also appear in the contexts of doctor–patient interaction and medical treatment. In particular, black American, Latin American, and lower income patients tend to receive poorer quality health care. While ethnicity and social class are often related, it is important to note there are differences in doctor–patient interactions based on social class alone. Patients with lower socioeconomic status tend to receive less medical information, less emotional support, and less encouragement to participate in the medical interaction and decision-making process (Verlinde et al., 2012).

When patients and care providers from different backgrounds interact, the quality of the health care generally suffers if they do not successfully overcome differences in culture and language (Ferguson and Candib, 2002). Patients from different ethnic or cultural backgrounds are less likely to generate empathy and establish rapport with the physician, which can lead to reduced participation and transmission of information and, ultimately, worse patient outcomes (e.g., satisfaction, adherence, and health). Cross-ethnicity doctor–patient interactions also tend to be significantly shorter in length, and many of these negative effects are most likely due to ethnicity-related attitudes and beliefs that supersede the interaction at hand.

Differential treatment of patients based on ethnicity may be unconscious or unintentional, but the physician's negative stereotypes, attitudes, and beliefs still have a direct effect on the quality of health care the patient receives. For example, black Americans received fewer recommendations for heart surgery, even though they demonstrated the same clinical need as other patients, and black Americans ultimately underwent fewer heart surgery procedures (Maynard et al., 1986). Furthermore, a study by DiMatteo et al. (2009) indicates there is an intersection between gender and ethnicity regarding health disparities, such that African-American women are disadvantaged even more than African-American men, and

gender and ethnicity concordance of the physician and patient appears to play a large role in this.

These disparities and patient reports of lower health care quality indicate physicians may simply neglect, ignore, underestimate, or otherwise fail to consider the needs, expectations, characteristics, and abilities of their ethnically or culturally different patients. Likewise, patients may have particular expectations and beliefs that are not expressed during the interaction. In both cases, the medical consultation may be unconsciously influenced by patient and physician behaviors (or lack thereof) that confirm preexisting attitudes, beliefs, or stereotypes held by either party. A patient's cultural background can determine what medical problems or symptoms are considered significant by the physician, as well as what medical problems or symptoms are presented or discussed in the first place. Ferguson and Candib (2002) suggest increasing the diversity of medical personnel and for majority status physicians to improve their relationships and communication skills with minority status patients. Similarly, cultural sensitivity training programs have been found to improve both the care provider's communication abilities and the patient's health outcomes (Majumdar et al., 2004). Different ethnicities and cultures communicate and cope with illness in distinct ways, so it is imperative that physicians are sensitive to both the common and distinct needs of various peoples.

Physical and Psychosocial Health

Aspects of the patient's health, more so than the physician's, can influence the doctor–patient interaction. There are a number of ways the patients' mental and/or physical health is correlated to how the physician and patient communicate with each other (see Hall et al., 1996). Sicker patients tend to offer more medical information to their care providers, and both parties discuss the possible factors of the illness more. However, there also appears to be less social conversation between both parties when the patient is ill or otherwise distressed, which may result in less provision and discussion of important psychosocial information, more overall dissatisfaction with the medical consultation, or the loss of many other intangible benefits of a healthier, more productive interaction between the physician and patient.

A patient's distress can increase the salience of their mental or physical illness, prompting more concern about the medical interaction at hand. This salience may ultimately lead care providers to respond differently to sicker patients. For example, physicians report liking their sicker patients less than their healthier patients (Hall et al., 1996). In conjunction with the lack of social conversation, this resembles the more physiological and less personal or participatory approach to the medical consultation. A similar issue occurs with patients of greater age, as older patients typically have more salient mental and/or physical distress or other medical problems. There are a number of characteristics that distinguish older patients from others (e.g., the more life-threatening nature of their medical problems), but research indicates interactions between physicians and older patients are less participatory and more focused on providing biomedical information (e.g., Kaplan et al., 1995).

Third Parties and the Internet

The lack of participation among patients who face obstacles to communicating with their care provider is common enough that companions or interpreters often join the medical consultation to facilitate a more patient-centered approach. Adding a third party can complicate, simplify, or otherwise influence the medical consultation in various ways (e.g., Ferguson and Candib, 2002). The general recommendation is to use professional interpreters to overcome culture or language barriers and increase access for those in need, but every physician might not display improved communication skills under these circumstances. Although the presence of additional medical professionals tends to relate to a lower quality of communication, there has been relatively little examination of exactly how the presence of patients' companions influences the dynamics of the doctor–patient relationship.

Perhaps one of the most significant third-party influences on doctor–patient interactions has been the increasing use of the Internet as a tool for medical information and/or communication. Editorials by physicians and researchers alike have questioned the appropriate use of media such as online social networks and their effects on traditional medical consultations. While these social networks can act as an additional channel of communication between the patient and the care provider, it appears that maintaining a professional relationship as well as individual privacy is achieved by physicians properly distancing themselves from their patients in this online space. Guidelines do exist regarding physicians' use of social media (e.g., American Medical Association, 2010), as there may be unintended consequences for the doctor–patient relationship if this new dimension of communication is not properly addressed.

Beyond acting as a medium of communication, the Internet can also be considered an intermediary of the doctor–patient interaction in the form of providing health information or medical recommendations. This up and coming 'triangulation' of the patient, physician, and Internet has been thoroughly reviewed by Wald et al. (2007), who propose that there is great potential for the Internet to improve medical interactions. Among the benefits the authors list are more informed health care choices, enhanced communication and information provision, increased partnership as part of a more collaborative approach, increased availability of social support, and even managerial gains such as better use of time during clinical visits and increased access to information like health records. The emerging role of the Internet in medical communication also means there are potential drawbacks, such as increased misinformation, intensified socioeconomic disparities due to limited Internet access, increased physician liability, and challenges to the physician's role or the basic dynamics of the physician–patient interaction; however, the authors and others (e.g., Medical Library Association, 2013) do provide suggestions on how best to integrate the Internet into the doctor–patient relationship.

Outcomes of the Doctor–Patient Interaction

Doctor–patient communication has been studied extensively with regard to various patient outcomes, including the

understanding and recall of medical advice and information, satisfaction with the medical visit, adherence to medical recommendations, sense of confidence and autonomy, trust in the care provider, and overall health. Aside from patient outcomes that may ultimately influence the patient's health, the quality of doctor–patient communication is also directly related to health outcomes such as increased recovery rates, decreased use of pain medication, shortened stays in the hospital, and improvements in physiological indicators such as blood pressure and blood sugar. Patient-centered and relationship-centered behaviors (e.g., being informative and supportive and building rapport and a partnership) are generally associated with improved health (e.g., symptom resolution). Although the medical interaction is predictive of a number of health outcomes, the thoroughly researched proximal variables of patient satisfaction and adherence are discussed in detail.

Satisfaction

Patient satisfaction can generally be defined as how well the patients' expectations are met by the actual care and treatment they receive throughout the medical interaction. Because patient satisfaction concerns the quality of health care received, it can be measured in reference to a number of health care aspects (e.g., a specific doctor or visit, access to and quality of the facility, technical skills and procedures used, and information provided). The present article discusses patient satisfaction regarding the physician's behavior, as this tends to be the aspect of patient satisfaction that is the most salient and influential.

Patient satisfaction is typically related to the doctor's communication style (i.e., doctor centered versus patient centered), with the patient-centered approach being related to more patient satisfaction than the doctor-centered approach. Both patients and physicians tend to be more satisfied when the physician uses a psychosocial approach rather than a strictly biomedical one. Patient satisfaction is related to physician's nonverbal communication abilities, as well. Physicians who are better able to encode (i.e., express) emotional nonverbal cues and decode (i.e., accurately interpret) emotional expressions of their patients tend to have more satisfied patients (DiMatteo et al., 1986). A higher degree of nonverbal immediacy (i.e., closeness demonstrated by behaviors like gazing, leaning forward, and affectionate touching) displayed by the physician is also related to higher ratings of patient satisfaction. These results are supported in a review by Lelorain et al. (2012), which found that greater empathy, as it is often related to or indicated by nonverbal immediacy and patient-centered care, is positively related to patient satisfaction.

Specific physician behaviors that tend to be associated with higher ratings of patient satisfaction include information giving, partnership building, positive talk, discussion of psychosocial aspects, social conversation, perceived confidence, and liking of and/or familiarity with the patient. Likewise, the more active role the patient plays, the longer the visit lasts, and the degree to which the physician takes a patient-centered or egalitarian approach to the medical interaction also predicts higher ratings of patient satisfaction. Factors related to decreased patient satisfaction include the degree to which the physician dominates the medical interaction, the amount of biomedical questions asked, and the poor health status of the patient. It is important to note that many of these factors of satisfaction and dissatisfaction may certainly co-occur and influence each other throughout the medical interaction.

Dissatisfied patients are less likely to return for future medical visits, follow medical regimens and recommendations, or develop a healthy doctor–patient relationship. The most dissatisfied patients are more likely to sue the care provider for malpractice. Interestingly, physicians are more likely to be sued for malpractice when the patient believes there was poor communication or an otherwise uncaring attitude rather than every instance that involves medical error. Levinson et al. (1997) found that, compared to doctors who had been sued for malpractice, those who never had a malpractice suit held longer visits, laughed more with their patients, and were more likely to use a patient-centered or egalitarian approach that emphasized the patient's active role and attempts for both parties to understand each other.

Adherence to Medical Advice

Medical visits, consultations, or other interactions generally result in some sort of recommendation by the care provider. Patient adherence refers to how well the patient follows the care provider's advice (e.g., taking prescribed medicine, undergoing suggested treatments, or making recommended lifestyle changes). Where the lowest levels of patient satisfaction can lead to malpractice suits, low patient adherence can be directly related to poor health outcomes. Overall rates of patient nonadherence are fairly high. Recent analyses (e.g., DiMatteo, 2004) indicate that adherence rates have been rising over the years, with some 50–75% of patients adhering to medical recommendations according to studies conducted after 1980. Incidentally, a study by DiMatteo et al. (2002) reveals that patient adherence is associated with health outcomes, meaning communication behaviors that improve adherence may indirectly improve the patient's health outcomes as well.

A significant part of patient nonadherence is due to the patient's lack of understanding medical information and advice or the physician's inability to communicate this information and advice properly. One meta-analysis (Haskard Zolnierek and DiMatteo, 2009) reveals that the quality of the physician's communication is significantly related to the patient's adherence, and patient adherence tends to improve when physicians are trained to be better communicators (e.g., through a patient-centered approach). Doctors have a tendency to overestimate the degree to which the patient is adhering to medical advice or following treatment and prescription guidelines. Additionally, adherence is rarely brought up as a topic of conversation, either by the patient volunteering information to the physician about their adherence or the physician asking the patient directly about adherence to the medical regimen.

As mentioned previously, the reciprocity of the positive or negative affect during the physician–patient interaction may have an effect on patient outcomes. For example, if patients feel particularly negative toward the physician – even if this was prompted by the physician's generally dissatisfied or negative

attitude – patients will be less likely to adhere to the medical advice they are given. Similar to the relationship between physician nonverbal sensitivity and patient satisfaction (DiMatteo et al., 1986), more sensitive physicians tend to have more adherent patients. Nonverbal sensitivity may be indicative of several other beneficial aspects of the doctor–patient interaction (e.g., a more patient-centered approach), and patients tend to be more adherent when they ask questions and the physician delivers information in a more understandable manner. The Information-Motivation-Strategy model highlights the most important mechanisms through which patient adherence is attained (DiMatteo et al., 2011). According to this model, the doctor–patient relationship should ensure that the patient accurately understands the medical recommendations, is properly motivated to accept the recommendations, and has the appropriate means, abilities, and/or support system to follow the recommendations.

Interventions for Doctor–Patient Interaction

Doctor–patient communication interventions primarily involve some sort of training of the patient or the care provider. Many efforts have been made to make the quality of the doctor–patient interaction salient to both patients and their care providers, and this tends to improve the patients' outcomes. Addressing the patients' concerns and providing the information they request in an understandable manner can prevent miscommunication and alleviate the negative effects of distressing news, for example. Over time, researchers as well as medical and educational institutions have come to understand communication training is a necessary aspect of medical care that improves the skills and abilities of the physician. Presently, communication skills are assessed or otherwise required by national licensing and accreditation associations in the United States, and many medical schools have incorporated training programs designed to improve communication skills (e.g., by encouraging physicians and residents to ask open-ended questions and increase nonverbal immediacy). Such training programs and interventions are essentially encouraging care providers to adopt a more patient-centered or relationship-centered approach. This stands in contrast to previous observations that, among more traditional medical school approaches, younger medical students were more likely to engage in a psychosocial patient-centered approach, but this tendency declined and became largely replaced by a biomedical doctor-centered approach as they progressed through the program. Despite the changes in medical education and practice, recent studies (e.g., Haidet et al., 2002) indicate this pattern of behavior has not disappeared over the years. Medical students still tend to display relatively less egalitarian, psychosocial attitudes and more doctor-centered attitudes as they progress through medical school, although the overall level of patient-centered attitudes in medical practice has still reasonably increased over time.

Interventions aimed at addressing physician's communication skills often lead to improvements in both the physician's abilities and outcomes such as the patient's satisfaction. As indicated by Haskard Zolnierek and DiMatteo's (2009) meta-analysis, training physicians' communication abilities may improve patient adherence through a number of means (e.g., transmission of information, encouragement of partnership and patient involvement, and providing a more open and supportive environment for discussion). Communication training has led to increased sensitivity to patients' psychosocial problems as well the ability to address such problems, and training has also been shown to improve the quality of the medical interaction by making the physician better able to relate to the patient, communicate empathy, and elicit information through a more psychosocial approach. Physician training appears to be an effective intervention, whether it is a single session that lasts a few hours or continuous training that lasts for the duration of medical school. A meta-analysis by Roter et al. (1998) reveals that physician interventions designed to improve adherence have positive effects on a variety of outcomes (e.g., severity of the illness, prescription refilling, and maintaining medical appointments) across a variety of diagnoses (e.g., cancer, diabetes, and psychological disorders). These interventions tended to work on a situational basis, but the authors do identify three broad categories of physician intervention strategies: educational (i.e., increasing patients' knowledge by teaching them and/or providing educational materials), behavioral (i.e., guiding behavioral patterns related to medical interactions through practice, skill-building, and modeling, for example), and affective (i.e., appealing to the patient's emotions and/or social support networks).

Interventions targeted at patients are also effective, as they generally encourage patients to become more active and involved in the medical interaction, promoting a more balanced, patient-centered or relationship-centered approach. Some interventions also attempt to address the patient's health literacy directly, and in contrast to the study by Wald et al. (2007), increasing the quality of health information technology can reduce health disparities. Providing patients with information such as an audio recording of the doctor–patient interaction or a written copy of their medical record has also shown promise in improving patients' understanding and recall of relevant medical information. However, most interventions aimed at patients attempt to improve the doctor–patient interaction by providing the patient with information or guides about communicating during the medical interaction (e.g., by encouraging them to ask more questions, seek more information, and take an active role in providing information). Interventions that provide patients with written information are indeed effective, but a review by Harrington et al. (2004) indicates patients participate in the medical interaction the most after receiving a face-to-face intervention or training session. In any case, face-to-face interventions in which someone personally reviews information and practices skills with the patient have been shown to improve health outcomes and the patient's perception of their health status.

Conclusions

Doctor–patient interactions are an unquestionably important aspect of the medical system. They are also multifaceted, multidimensional, and still in need of much more research before more definitive conclusions and suggestions can be

made regarding how to improve and better understand them. Nevertheless, the present article attempts to provide a basic explanation of the number of psychological influences on, components of, and effects resulting from the doctor–patient interaction. The patient-centered and relationship-centered approaches that incorporate the entirety of the personal and psychosocial aspects of the individual (i.e., a balanced use of biomedical or evidence-based information) are generally considered to be a vast improvement in medical practice. Research that further contextualizes variables related to the physician, patient, and interaction across a number of health care situations, procedures, and environments may be able to provide more consistent improvements in the quality of health care delivery, as seen in the case of widespread increased physician communication training over the years. Aspects of doctor–patient interactions and health care delivery gradually change just as society changes, and effective health care relies on continued efforts to understand how these changes affect the medical interaction and how to address such changes in meaningful ways. Perhaps one of the most impending challenges for doctor–patient communication is how to incorporate the Internet and other advancing technologies in a useful manner. Accentuating the positives and eliminating the negatives of this emerging third-party influence may ultimately provide a new level of quality in doctor–patient interactions, but this will require a continued progression of research and practice.

Documentary and Ethnographic Film

Kizhavana P Jayasankar and Anjali Monteiro, School of Media and Cultural Studies, Tata Institute of Social Sciences, Deonar, Mumbai, India

Abstract

Documentary film is defined in terms of its difference from other genres of nonfiction film and from fiction film. John Grierson first employed the term 'documentary,' which he regarded as "a creative treatment of actuality" (Grierson, cited in Barnouw, 1974: p. 287). Ethnographic film belongs to the domain of cultural anthropology, which traditionally involved the study and scientific observation of communities. This article presents a brief history of documentary and ethnographic film with authorial positions as the organizing principle. Debates about these genres revolve around relationships between the author and the narrative, between the author and the subject filmed, and between the narrative and audiences.

Documentary and Ethnographic Film

The term documentary came into usage in the nineteenth century as an adjective referring to documentation, hence with connotations of evidence (Rosen, 1993: p. 6). With reference to film, it was first employed by John Grierson (in his 1926 review of Robert Flaherty's film *Moana*) to indicate a body of work that documented reality, involving "a creative treatment of actuality" (Grierson, cited in Barnouw, 1974: p. 287). The twin roles of the documentary filmmaker, as a creator with an agenda and as a purveyor of 'actuality,' have been at the root of several debates concerning the truth claims of the documentary. In some accounts, documentary film is still regarded as indexically representing a real world, mimetically reproducing pictures of reality with a view to providing knowledge about it, as is the case in any scientific endeavor.

On the one hand, developments in imaging technologies have perfected hardware and software enabling the unobtrusive documentation of reality; on the other, the very notions of 'documentary' and 'reality' have undergone radical reformulation. In theory and practice, the truth claims of documentary and its status as 'evidence' of a given historical world have increasingly been problematized in the contemporary postdigital cultural context. Over time, documentary film has come to embody diverse modes of negotiating the complex set of relationships between the author, the film text, the audiences, and the world.

Ethnographic film comes under the rubric of cultural anthropology, which traditionally involved scientific observation and recording of the lives and cultures of other races, usually indigenous communities in colonized lands. Jean Rouch terms anthropology as "the eldest daughter of colonialism" (cited in Winston, 1993: p. 51), thus foregrounding the inherent relationship of power that underpins any encounter between the anthropologist and the other. The premise that ethnographic film is a value-free, indexical scientific record has been subjected to critical interrogation and revision, leading to dramatic changes in its theory and practice.

Demarcating the Terrain of Documentary Film

Documentary versus Other Nonfiction

Documentary film has been regarded as a specific body of work under the broader rubric of 'nonfiction' film. The latter includes genres such as the first 'actuality' films of the Lumiere brothers, the newsreel, the travelogue, and the educational film. These genres, while sharing in common with documentary the use of actuality footage, have been seen as distinct because of the differing context of their production and use (Barsam, 1992). Though documentary and ethnographic film occupy distinct terrains within nonfiction film, the issues confronting both share a great degree of commonality.

Documentary versus Fiction

The fiction film, to which the documentary and other nonfictional genres were opposed, involved an obvious process of construction to offer an illusion of reality. The documentary filmmaker, however, bore the onus of providing a window to the world. The twin positions eschewed by the documentary filmmaker were that of the 'manipulative' creator of fiction, on the one hand, and the didactic educator on the other. The control and omnipotence represented by both these positions, which 'told' audiences about an external reality, was rejected in favor of a position that purported to 'show' its viewers the world.

Toward a Taxonomy

The wide array of themes, styles, formats, and modes of address employed by documentary filmmakers make it difficult to construct an inclusive typology that accounts for this variety. Barnouw (1974), for instance, chooses to classify documentaries on the basis of the role of the maker (explorer, reporter, advocate, poet, observer, guerilla, and so on), while emphasizing that these roles are not mutually exclusive. However, certain roles have been privileged at certain historical moments, making it possible to construct a typology on this basis. Barsam (1992) follows a classification employing time and space (American/British/European and Asian, at various periods of time).

Nichols (2010) identifies six modes of representation. The expository mode, used by many of the early filmmakers, such as Grierson and Flaherty, as also in current television network news, tends to use 'voice-of-God' commentary or poetic narration to inform or enlighten the viewer about the world outside. The argument of the commentary is what propels the text, the visuals serving more as illustration or counterpoint.

 http://dx.doi.org/10.1016/B978-0-08-097086-8.95013-X

The expectation of the viewer is generally to obtain certain, authoritative knowledge about reality, to understand cause and effect, problems and solutions. Recent examples of this mode include *The Corporation* (2003) by Mark Achbar and Jennifer Abbott, and *Grizzly Man* (2005) by Werner Herzog.

The poetic mode treats narratives differently, with little commitment to representing actuality or presenting facts. With its emphasis on affect and the expressive dimensions of cinema, it "stress[es] visual and acoustic rhythms, patterns, and the overall form of the film" (Nichols, 2010: p. 150). *Koyanisqatsi* (1982) by Godfrey Reggio, a purely visual narrative set to the music of Philip Glass, represents this mode.

The observational mode (also referred to as Direct Cinema) was facilitated by the invention of lightweight equipment with synchronous sound recording capability. It rejects the relatively didactic stance of the expository mode, in order to bring to viewers, life as it unfolds. The filmmaker aspires to the role of a detached observer and "look[s] on as the social actors go about their lives as if the camera were not present" (Nichols, 2010: p. 150). The expectation of the viewer is to gain privileged access to an unmediated external world. *Control Room* (2004) by Jehane Noujaim, on Al Jazeera's reportage of the US–Iraqi war, is a recent example of such work.

The participatory mode also draws on the availability of mobile equipment, but rejects this detachment in favor of a more interventionist role. The filmmaker's relationship with the subjects of the film comes to the fore and is not invisible, as in the observational mode. The focus in on local knowledge; the filmmaker is not confined to creating continuities in time and space, but could employ unusual juxtaposition, archival material, and other devices in constructing the narrative. The viewer's expectations are situated in the realm of the interpretative, since the mode makes no claim to absolute truth and neutral knowledge. Nichols (2010) cites the films *Fog of War* (2003) by Errol Morris and *Enron: The Smartest Guys in the Room* (2005) by Alex Gibney as exemplifying this mode.

In the reflexive mode, the act of representing the world itself becomes central to the film's narrative. The premises from which the narrative is constructed and the process of construction are available to the viewer. While it bears some resemblance to the participatory mode, the reflexive mode, in addition to problematizing the relationship between the filmmaker and the subjects, also problematizes the relationship between the narrative/filmmaker and the viewer. The camera is not an evidence gathering apparatus. The conventions of realism, when used, are interrupted and put to question. Broadly speaking, the reflexive mode draws on the post-structuralist critique of the indexical and instrumental view of language and the speaking subject (*see* Semiotics). Trinh T. Minh-ha's *Reassemblage* (1982) and Elizabeth Barrett's *Stranger with a Camera* (1999) are reflexive documentaries.

The performative mode problematizes the idea of knowledge as universal and abstract, affirming an understanding of knowledge that is embodied, evocative, and experiential. In cinematic terms, it plays with a combination of the "actual and the imagined" (Nichols, 2010: p. 202) in order to convey a visceral sense of the subjective world of the filmmaker. *The Gleaners and I* (2000) by Agnes Varda, *Bontoc Eulogy* (1995) by Marlon Fuentes, and *Tongues Untied* (1989) by Marlon Riggs represent the performative mode.

A Brief History of Documentary and Ethnographic Film

The theoretical positions and the narrative strategies within the discourse of the documentary film have undergone fundamental changes, making it impossible to establish continuity across them. In spite of this apparent diversity, they could perhaps be classified in terms of the notions of authorship and viewership that they are, implicitly or explicitly, putting forth or negating. A useful device in establishing intelligibility across the vast corpus of documentary and ethnographic film practice is, therefore, to look at the various authorial stances that inform it. This, by no means exhaustive, historical account explores the work of major figures and movements, which contributed to the development of new conventions, styles, and norms within documentary film.

The Author as Reconstructing the Authentic Other – Robert Flaherty

Flaherty's *Nanook of the North* (1922), which celebrates the heroic struggle for survival of its Inuit protagonist, could perhaps be regarded as the first ethnographic film. Flaherty 'manipulated reality' in order to reveal what he regarded as the 'true spirit' of the culture. Unlike later ethnographic work, which trod the path of 'flat' scientific documentation, Flaherty's work, whose narrative strategies involved his subjects in dramatic reconstructions of their own lives could be regarded as "a doorway one could step through imaginatively into the life of another people" (MacDougall, 2005: p. 232). MacDougall traces this 'other' lost vision of visual anthropology, which was later reclaimed, by Jean Rouch and John Marshall. In hindsight, his work has been critiqued for its mythologizing of the 'noble savage' and its elision of the 'real' social and political circumstances of his subjects' lives. Flaherty's work poses questions about the nature of 'truth,' the relation of the documentarist to the 'reality' he/she creatively appropriates, and the politics of representing the other.

The Author as Social Educator – John Grierson

Grierson's extensive writings on the place, function, and codes of the documentary regard it as performing the function of educating and involving citizens in democratic civil society. In 1930, Grierson established the Empire Marketing Board Film Unit, later to become the General Post Office Film Unit. This was a nucleus for the work of documentary filmmakers such as Basil Wright (*The Song of Ceylon*, 1934, *Night Mail*, 1936, codirected with Watt), Harry Watt (*North Sea*, 1938), Alberto Cavalcanti (*Pett and Pott*, 1934, *Coalface*, 1935), and Humphrey Jennings (*A Diary for Timothy*, 1944). The themes handled included the lives of working people; social problems related to health, housing, and unemployment; and wartime propaganda.

The Author as Reflexive Roving Eye – Dziga Vertov

Denis Arkadievitch Kaufman called himself Dziga Vertov, meaning 'spinning top.' His writings and films were produced in the context of the post-Revolution ferment in the Soviet

Union. His work, influenced by Futurism, represents a seminal contribution to film theory and practice, repudiating all pre-existing forms of cinema. Vertov regarded the cinematic way of seeing, the 'Kino-Eye' as establishing a radically different relationship with reality, making the "invisible visible, 'turning' lies into truth, 'propagating' the communist decoding of reality." His work on the Kino Pravda series, among others, and his film *The Man with the Movie Camera* (1929) created much debate and controversy for its formal illusionism, its subjectivism, its radical play with elements of picture and sound, so that a sense of dislocation from reality is achieved. Its reinvention of cinematic language in a mode, which reflexively foregrounds the act of construction and directly interpellates the viewer with revolutionary fervor stands as unique and perhaps far ahead of its time.

The Author as Propagandist – Leni Riefenstahl

Leni Riefenstahl is known for her documentaries that mythologized the politics of German National Socialism. While her work is noteworthy for its aesthetic virtuosity, it raises questions of the politics of aesthetics. *The Triumph of Will* (1935) documents the 1934 National Socialist rally in Nuremberg, a spectacular celebration of the myth of fascism. Sontag (1982) discusses how the actuality of a film like *The Triumph of Will* was constructed through carefully choreographed rituals of domination and enslavement that contrast the hypnotic presence of the omnipotent leader with the faceless regimentation of large masses of ordinary people.

The Author as a Fly on the Wall – Direct Cinema

Direct Cinema represents a significant departure in the American documentary of the 1960s. The term Direct Cinema is sometimes used interchangeably with *cinema verité* (from which, however, it is distinct). It positions the author as an unobtrusive observer, thereby attempting to reclaim the evidentiary project of documentary film. The camera as well as the filmmaker occupies neutral positions, endeavoring, "to convey [to the viewer] the feeling of being there" (Leacock, cited in Winston, 1993: p. 43). The invention of lightweight equipment with synchronized sound was first utilized by Drew Associates to produce *Primary* (1960), on the election campaigns of John F. Kennedy and Hubert Humphrey. Drew collaborated with Richard Leacock, Pennebaker, and Albert–Maysles in the making of this film. The filmmakers had themselves perfected the technology and the now legendary shot of the camera following Kennedy through the crowds on to the podium, shot by Maysles, demonstrated the versatility of the new technology.

The then prevailing dominant empirical traditions of the scientific method, which took sides with the 'body,' in an age old debate on its antithetical position to the 'mind,' was at heart of the positioning that the proponents of Direct Cinema aspired toward. The dichotomies of mind–body and subject–object held center stage, not only in the debates on documentary cinema, but also in the discourses of the social sciences and linguistics.

The truth claims of the proponents of the American Direct Cinema did not pass uncontested. In response to its critics, the movement of Direct Cinema had to allow for subjectivity, while retaining its claim to authenticity. Frederick Wiseman, who terms his work "totally subjective," represents a new denouement in the Direct Cinema debates. While the work of Leacock and Pennebaker focused on portraiture and recording of events, Wiseman's work investigates various institutions such as hospitals, high schools, and prisons, revealing patterns of behavior, which raise disturbing questions about institutional morality and social values. His first film *The Titicut Follies* (1969) was an indictment of an institution for the criminally insane and saw him embroiled in legal controversy. Wiseman does a tightrope walk between the subjectivity of the filmmaker and the imperative to provide the viewer with fair evidence so that he/she can make up his/her own mind on the reality that is represented.

The Author as a 'Fly in the Soup' – Cinema Verité

Henry Breitrose (cited in Winston, 1993: p. 53) uses the interesting analogy of a 'fly in the soup' to describe cinema verité (a term borrowed from Dziga Vertov). In contradistinction to Direct Cinema, cinema verité resolves the question of objectivity by situating the filmmaker as an *agent provocateur*. The work of Jean Rouch and Edgar Morin typifies this stance. Rouch's *Moi, un Noir* (1959) represents a turning point in ethnographic film; in this film, the role of the camera shifts from a recording device to a precipitator of action. The film presents the inhabitants of Treichville, playing out scenes of their choice for the camera. After viewing themselves on screen, they reflect on the recorded events, reinterpreting them. This complex and novel process of representation explored a new relationship among the filmmaker, his subjects, and the narrative. Rouch's project was rooted in an attempt to redefine the relationships of power in ethnographic filmmaking, which had hitherto been a colonial gaze at the other. *Chronique d'une Été* (1961) in a reversal of ethnographic roles, turns the camera on "the strange tribe that lives in Paris" (Morin cited in Winston, 1993: p. 51). Rouch's notions of a "shared anthropology" (Rouch and Feld, 2003) involving dialogue across cultures and 'ethnofiction' subverted the colonial gaze and reshaped the terrain of ethnographic film.

The Postcolonial 'Other' as Author

Indigenous documentary film production in the postcolonial context was sometimes State-sponsored (as in Cuba and India) and often projected the dominant agenda of modernity. Over time, the rise of independent documentary production gave voice to marginal groups and looked critically at larger political questions. The work of Fernando Solanas and Octavio Gettino in Argentina (*Hour of the Furnaces*, 1968), Patricio Guzman (*The Battle of Chile*, 1974–79), Santiago Alvares in Cuba (*Now*, 1965), Nana Mahomo in South Africa (*Last Grave at Dimbaza*, 1975), Anand Patwardhan (*Father, Son and Holy War*, 1998) in India are but a few examples of a vibrant tradition of political engagement. The technology of video and the possibility of broadcast by international television networks have created a market for stories from the South. Many independent documentary filmmakers in the South are dependent on these markets for support. The market demand tends to privilege

images that present the other as exotic, oppressed, or disaster-ridden. Raul Ruiz's *Of Great Events and Ordinary People* (1979) ironically comments on this endless dividing practice that sustains international documentary production and consumption.

The 'linguistic turn' within postcolonial ethnography, which regards the ethnographer as an author constructing narratives, has led to a rethinking of the relationship between the ethnographer and his/her informants. Since this perspective attempts to render apparent the process by which the narrative is produced, the informants in a sense become coauthors. Given the unequal power flows between the ethnographer and his/her informants, various modes of integrating the voices of the other in ethnographic texts have been explored. Some of these have involved the informants taking control of the medium to construct representations of themselves. The Navajo project, initiated in 1966, by Sol Worth and John Adair, was an experiment in teaching the Navajos, in Pine Springs, Arizona, to use the technology of filmmaking. The attempt was to understand the modes of representation that were at work in the narratives produced by the Navajos (Worth and Adair, 1970).

Eric Michaels (1994) explores the space of alternative production and distribution by the Warlpiris. The project, initiated in 1985, involved local production and illegal transmission by the Warlpiri Media Association, at Yuendemu, in Central Australia. Michaels identifies significant differences between aboriginal and European creative practices. These pertain to "ideological sources and access to inspiration, cultural constraints on invention and imagination, epistemological bases for representation and actuality, indistinctness of boundaries between authorship and oeuvre and restrictions on who makes or views expressive acts" (Michaels, 1994: p. 105).

The Reflexive Author

The reflexive mode, already discussed earlier, gained prominence in the 1970s and 1980s. On the one hand, it was a response to the current debates on language and signification, subjectivity and ideology, involving formal strategies that question the "materiality of the cinematic signifier" (Wollen, cited in Nichols, 1991: p. 65). On the other hand, it arose in the context of movements (feminist, civil liberties, gay and lesbian, revolutionary struggles in the Third World, and so on) that questioned the "materiality of social practice" (Wollen, cited in Nichols, 1991: p. 65). The films of Chris Marker (*Sans Soleil*, 1982), Errol Morris (*The Thin Blue Line*, 1987), Michael Moore (*Roger and Me*, 1989), Jill Godmilow (*Far from Poland*, 1984) are few examples of emerging trends. Nichols (1991: p. 65) points out that reflexivity is not merely a matter of formal narrative strategies, but an engagement with the marginal and alternative ways of seeing and acting in the world. Examples of such politically reflexive films are Georges Franju's *Blood of the Beasts* (1949), Emile de Antonio's *In the Year of the Pig* (1969), Wiseman's *High School* (1968), and Joris Ivens' *The Spanish Earth* (1937).

The early independent women's films (*Union Maids*, 1976, *Joyce at 34*, 1972, and *Janie's Janie*, 1971) were situated within the realist tradition, and made as tools for consciousness raising and mobilization (Kaplan, 1982–1983). Semiological film theory tends to dismiss the radical potential of these films, a view that is contested by Kaplan, who argues that "the same realist signifying practices can indeed be used to different ends" (Kaplan, cited in Nichols, 1991: p. 68) and that a consideration of the strategies of reception is also important (*see* British Cultural Studies). Feminist films such as Mitchel Block's *No Lies* (1973), Michelle Citron's *Daughter-Rite* (1978), problematize cinema verité techniques by drawing the viewer into an illusion of reality, only to reveal at the end that the narrative was scripted and the protagonists are actors.

Postfeminist work attempts to rewrite feminist themes to break away from the white/middle class/heterosexual character of the women's movement in the West. Trinh T. Minh-ha's *Surname Viet Given Name Nam* (1989), for instance, contests the systems of representation at work in a patriarchal ethnography, rejecting an essentializing of the heroic, suffering Vietnamese woman.

Contemporary Issues

Debates regarding documentary and ethnographic film have revolved around various sets of relationships: between the author and the narrative (the question of realism), between the author and the subjects filmed (the question of the ethics and politics of representation), and between the narrative and audiences (the question of effects and audience reception). An issue that has received relatively less attention is the question of how mass media institutional dynamics, the economics of documentary production, and the structures of distribution have influenced the politics and aesthetics of documentary production (*see* Media Imperialism; Television Industry; Internet and Culture). For instance, the fact that television constitutes a major market for documentaries tends to set the agenda for documentary film production and its reception. Today, the emergence of new forums for sharing and distribution based on the Internet such as YouTube and Vimeo are changing traditional modes of production and reception of documentaries. These new modes are, in some cases, able to resist regimes of control and censorship imposed by the State and the markets. Crowd funding is a new way of raising resources for the production of independent documentaries. The Internet serves as a platform for innovative production processes that work with found materials to generate documentary narratives, again bringing to focus issues of authorship and intellectual property rights. *Life in a Day* (2011) produced by YouTube constructed from 80 000 submissions of crowd-sourced footage from 192 countries revises traditional notions of authorship and dissemination.

The association of documentary and ethnographic film with scientific observation and evidence has shifted toward an engagement with the affective dimensions of the genre. Rutherford (2011) among others, points to the notion of 'mimetic innervation' (drawing on Walter Benjamin and Michael Taussig) to understand how the documentary can move away from the space of rationality to engage the viewer in a visceral, embodied relationship with the text, in a performative mode.

With new technologies, such as digital image manipulation and inexpensive portable video camcorders that are redefining

the realm of the real, the project of recording reality has never been more problematic. In postdigital, hyperreal cultures, a variety of other genres, ranging from reality programming on television to fiction films, have begun to appropriate the idiom of the 'real,' blurring the divide between fictional and nonfictional narratives. When the technology for appropriating actuality in the Direct Cinema dream became a reality, it is this very actuality that has become more and more elusive, which has made the landscape of documentary and ethnographic film complex, varied, and in a state of eternal reinvention.

Domestic Violence: Legal Perspectives

Yvana LBH Mols, Emory University School of Law, Atlanta, GA, USA

Abstract

The emergence of domestic violence (DV) as a legal issue in the 1960s has had international implications for law and policy. Legal recognition has manifested in various forms: criminal penalties for batterers, restraining orders, availability of tort remedies for survivors, and the attention of international human rights law. Even so, DV remains a pervasive harm worldwide. Courts are limited in their ability to address structural social problems because they are largely focused on individual redress. International treaties focused on human rights may provide individual causes of action and remedies, and express social priorities for peace and equality. Vulnerability theory addresses these structural issues of power and control with the goal of providing substantive equality and eradicating violence.

Introduction

Domestic violence (DV) as a legal concept provides an aspirational and broad, gender-, age-, and sexual orientation-blind framework for addressing private violence and has begun to make visible what has long been invisible. While the term may widely refer to child abuse and other types of family violence, this article will focus on violence between adults in a romantic relationship and use DV to refer to what is commonly known as intimate partner violence (IPV); other types of family violence are treated elsewhere in this volume. In contexts focusing on the relevance of gender in this type of abuse, 'woman abuse' or 'wife abuse' are sometimes used (Dragiewicz, 2011). There is disagreement about the gendered nature of DV, however; some argue there are 'nonpatriarchal' societies, such as the US and other democratic countries, where resort to violence by women is as common as it is for men (Dutton, 2006). The difficulties in defining the problem, identifying the perpetrators, and even deciding upon the language to describe the problem make what is commonly known as DV a constantly shifting target, presenting substantial challenges for the law.

This article is divided into five major Parts. Since violence against women historically has been the more trenchant problem, it will be the focus of this article. Following the introduction, the roots of DV as a private family matter and its rise as a legal issue are discussed. Part two addresses the treatment of DV as a criminal matter beginning with law enforcement, through prosecution, adjudication, and rehabilitative strategies. Part three considers DV as a civil matter, focusing on tort causes of action and remedies such as protective orders. Part four explores the role for international law, especially human rights law, in addressing DV as a global problem. Part five highlights trends and challenges in DV law, including the use of battered women's syndrome, and the problems with language inherent in the field.

History of DV in the Law: From Private Prerogative to Legal Issue

DV, while an ancient phenomenon, did not exist as a legal issue for much of human history (Ferraro, 1996). This was due to a sharp public private divide; public matters were subject to legal regulation, whereas private matters, including violence in the home, were left for informal familial or community rule (Natarajan, 2007). While some nations retain this binary and continue to neglect DV as a legal issue, many nations have revised notions of privacy in favor of protecting victims of DV (Natarajan, 2007).

The Anglo-American experience is illustrative of larger worldwide trends. English common law protected a husband's prerogative and his 'privilege' to punish or chastise his wife. This legal protection was grounded on the marital unity doctrine, which made the husband answerable for his wife's public behavior (Siegel, 1996). America's adoption of the marital unity doctrine also included the implicit condoning of DV, even while it was legally and formally prohibited. In the 1600s, the Massachusetts colony prohibited violence in the pursuit of family preservation, but this was largely unenforced, especially because the violence was perceived as socially permitted wife control (Buzawa and Buzawa, 2003). This justification was dependent on the high value of domestic privacy, which sanctioned or ignored otherwise criminal behavior based on the relationship of the parties (spouses), and the location of violence (the home). When wives failed to conform to the ideal of submissive womanhood, violence was considered an appropriate means of control (Rambo, 2009). Community governance of DV in the United States ended with the rise of the temperance movement in the 1920s. Though there was a rise in legal recognition of DV and a greater concern with holding perpetrators accountable, the temperance movement attributed DV exclusively to alcohol abuse and thus suggested that the elimination of legal access to alcohol would end violent behavior (Rambo, 2009). This framing marked DV as an individual matter of drunken belligerence, rather than a social or community-wide problem.

The social and governmental value of privacy provides additional grounds for the practice of DV in many places. The US Supreme Court, for example, has found the negative right to privacy implicit in the Constitution (Griswold, 1965) and embedded in a Western philosophical tradition that affirms the patriarchal family. Privacy also is considered socially desirable in many places, although some have held that the traditions around privacy obscure that it is inextricably connected to gendered, racial and class-based presumptions (Rambo, 2009).

In Africa, the history of DV as a private matter is inextricably linked with colonial influences. European colonial officials presided over cases that were a threat to public order and thus deemed 'crimes,' while leaving other cases to the jurisdiction of existing native authorities. Defined as a private matter, DV and family disputes were not considered crimes and would be handled by native authorities, if at all (Burrill et al., 2010). The turn to privacy usually means that the state tacitly accepts DV (Schneider, 1991). Thus, even as individual instances of violence are prosecuted, the logic of a right to privacy results in the structural problem of DV remaining invisible.

The formation of a battered women's movement in response to the privacy concern began with grassroots activism in the 1960s and 1970s. It challenged the tacit acceptance of DV as activists contested notions of family privacy, and prioritized citizen safety over another's right to nonintervention in domestic matters. As the movement gained traction, various states adopted legal protections for victims/survivors: criminal penalties for batterers, civil restraining orders, and other equitable measures. As the worldwide movement to eradicate DV grew through the end of twentieth century, many countries supplemented local laws by signing on, sometimes with reservations, to international treaties that defined DV and proposed legal frameworks (Burrill et al., 2010).

Criminal Aspects of DV

DV is largely covered by state and local laws, whether handled as a criminal or civil matter.

Arrest

Many crimes like homicide, assault, criminal contempt, stalking, and rape may have a DV component. However, the DV context may make arrest more difficult for officers, because the physical harm may be low in proportion to the psychological harm to the victim, and because there may be few witnesses to the violence (Buzawa and Buzawa, 2003; Sack, 2004).

The 'mandatory arrest' movement attempted to address the structural gaps in police enforcement of DV crimes. It began following a 1984 Minneapolis study by the Department of Justice, which showed that arrest of the offender was more successful in reducing DV recidivism than the interventions of mediation and removal of the offender for 8 h (Sherman and Berk, 1984). Following this study and the 1984 US Attorney General's report recommending arrest as the standard law enforcement response to DV calls, arrests for these crimes rose dramatically in the US (Sack, 2004). Mandatory arrest still requires police officers to establish probable cause for an arrest, but their discretion as to whether to arrest or mediate the situation has been curtailed: they must make an arrest if probable cause exists (Combs, 2006).

Community plays an important part in the success of mandatory arrest as a deterrent to future battering. For 'good risk' offenders with strong community ties, arrest is likely to deter recidivism due to social stigma, though 'bad risk' offenders with few community ties are unlikely to be deterred, and in fact more likely to escalate battering (Mills, 1998). Mandatory arrest policies may also lead to either dual arrests or the arrest of the victim of violence if an officer is uncertain about who initiated the violence (Sack, 2004). For women in poverty who may be economically dependent on their batterers, mandatory arrest may breed controversy and alienation for both victim and batterer (Brown, 2012).

A study done in 2005 in 10 Latin-American countries, including Belize, Bolivia, Costa Rica, Guatemala, and Peru, found that law enforcement official's attitudes toward DV and women often are based on harmful stereotypes and myths (Sagot, 2005). In many of these countries, these attitudes translate to real obstacles for survivors of DV and survivor mistrust of official channels of arrest and prosecution. Some specific issues are lack of specialized personnel, time-consuming and difficult-to-navigate bureaucratic processes, and inadequate response to emergency situations (Sagot, 2005). Availability of arrest is also complicated by the fact that crimes are defined in these countries retrospectively based on the nature of the injury suffered: an action is a crime if it results in an injury that takes more than 10 days to heal (Sagot, 2005). Psychological, other nonphysical, or fast-healing injuries are classified as misdemeanors and are treated similarly to civil actions (Sagot, 2005). Hostile attitudes, laws, and processes mean that law enforcement institutions are practically inaccessible for many DV survivors (Sagot, 2005).

In response to this problem of access to effective and sympathetic law enforcement, countries in Latin America and in India have developed women's police stations (WPS), staffed by officers specifically trained to address DV cases (Sagot, 2005; Natarajan, 2005). This initiative began in Brazil in 1985, and WPS have become widespread in Latin America with more than 475 now in Brazil (Women Police Stations Case Study, 2011). In India, WPS, called 'All Women Police Units,' were developed as a pilot project in Chennai in 1992, and have now spread across the country, numbering 442 on 1 January 2011, and located in 10 of 23 States and Union Territories (Joshi, 2012). WPS deal mainly with crimes against women and may provide holistic services that include arrest powers, as well as powers to distribute resources, provisions, and counseling (Sagot, 2005).

Prosecution

Prosecutorial reticence is a structural problem in DV cases. Office policies about what cases to prosecute and how to value victories have restrained some prosecutors' interest in pursuing DV cases when compared to cases involving stranger violence. Sometimes prosecutors and judges are simply not well-versed in the law. For example, a group of female judges in Uganda noted that DV was being underenforced due to unawareness of the law, apathy for enforcement of a so-called 'women's issue,' and the failure of the state to provide additional resources for implementation (Goitom, 2013).

Where victims of a crime are not parties to a case, as in the US, the victim does not have control over the decision to file or how the case should proceed once filed. Survivors who do not want their abuser prosecuted or later change their mind about the benefits of prosecution have little power to influence the decision, beyond refusing to give evidence in an attempt to weaken the case and likelihood of success (Cretney and Davis, 1996). While victim testimony is often crucial to prosecuting

crimes, prosecutors often go forward on the basis of physical evidence, police and medical records, and other witness statements, sometimes used to impeach the victim now resisting prosecution. (Goodmark, 2011).

Further curtailing victim control over prosecution and prosecutorial reluctance to pursue DV cases was the institution of 'no-drop prosecution' policies. No-drop policies vary in their coercive power against victims. 'Soft' no-drop policies address victim's concerns about prosecution and facilitate testimony by providing support and explanation, but stop short of actually compelling testimony. On the other hand, 'hard' no-drop policies compel victims to testify; hard no-drop policies thus embody the view that the state has a more compelling interest in controlling the victim than does the abuser (Goodmark, 2011).

The efficacy of nondiscretionary policies is up for debate. Some people claim that they are good for society and for the criminal justice system, because they punish and deter criminals instead of vindicating individual victims' wishes; they facilitate safety for victims by removing them from the coercive power of their attackers; and they empower victims who experience the efficacy of the criminal justice system (Goodmark, 2011). But DV advocates have challenged mandatory arrest and prosecutorial no-drop policies as harmful for victims' safety and autonomy. A Harvard University study found that mandatory arrest made revictimization by one's batterer more likely and increased intimate partner homicides by nearly 60 % (Iyengar, 2007). Taking away police officers' and prosecutors' discretion has the effect of disregarding DV victims' assessments of the situation from a safety perspective, as well as their choices about whether to press charges. These policies may result in a decline in reports of DV. In addition, stereotypes that attach to class and racial presentation may block justice for victims who do not fit a white, middle-class norm and lead to further marginalization of people of color (Brown, 2012). Thus, states' attempts to address the pervasive issues of DV may have the unintended consequence of disempowering the individuals experiencing DV. Even so, mandatory arrest policies remain law in many US states even after the 2005 Violence Against Women Act (VAWA) retracted its mandatory arrest endorsement in favor of merely a 'proarrest' posture (VAWA, 2013).

Doctrinal Changes

Various jurisdictions have attempted to address the low conviction rate for DV crimes by creating separate DV crimes, or by using DV as an aggravating factor. These laws may have different elements, different standards of proof, or harsher penalties when there is a DV aspect to the crime.

But the tendency to view DV within a criminal framework has also spawned a growing population of 'survivor-defendants.' These are individuals who were, at the time of their arrest, survivors of DV, and for whom DV was a contributing factor in their use of illegal violence against their intimate partner (Kraft-Stolar et al., 2011). This has led to the controversial use of 'battered women's syndrome' expert testimony to aid the defendant's defense claim.

Battered women's syndrome evidence is used by criminal defendants who have harmed or killed their abusive partners and seek to claim self-defense. It may also be used as evidence in cases of duress, or to mitigate murder to manslaughter. This syndrome is marked by the battered individual's perception of a predictable cycle of abuse: tension building, battering, and contrition (Walker, 1979). This cycle is used to explain why the victim may not wait until a period of acute battering to attack his or her batterer, as is customarily required for the objective reasonableness prong of many defenses (Walker, 1979). This syndrome, and its use in criminal defense, is controversial. It helps explain the reasonableness of a victim's anticipation of future harm, and the need to engage in self-defense, even when not under acute attack (Goodmark, 2008). It also provides convenient shorthand for describing common features of many DV experiences. However, critics claim that precisely because the experience of DV is multiple, varied, and complex, it does not lend itself to a single normative standard. Particularly excluded are women who do not fit the white, passive, middle-class, heterosexual norm (Brown, 2012). Others critique the syndrome language as pathologizing victims of DV to render their objectively unreasonable perceptions reasonable (Kinports, 2004).

Courts

The systemic failings of DV policies challenge judicial systems around the world. Because the causes and consequences of DV are multifaceted, recourse to traditional judicial remedies is often ineffective for ameliorating abuse, necessitating a holistic approach coordinating the efforts of community resources, law enforcement, prosecutors, and the judiciary (Shaffer, 2004).

It is argued therapeutic courts would provide this holistic support – a forum for coordinating community resources like mental health and substance abuse treatment, and providing continuing review and accountability (Shaffer, 2004). These courts focus more on rehabilitation than adjudication, and on the provision of services rather than on punishment. Cooperation and coordination between stakeholders is essential for successful therapeutic courts, though victim engagement in the prosecutorial process remains a lingering challenge (Labriola et al., 2009). They also provide a venue for efficient sanctions in the event of failure to comply with a court order, since long-term monitoring is built into the structure of the court (Shaffer, 2004).

Countries that trivialize the problem of DV through official's attitudes, if not through formal law, may provide informal judicial processes that exacerbate violence. For instance, in the 10 Latin-American countries studied in 2005, many resort to conciliatory processes that lend themselves to hard-to-enforce, out-of-court agreements (Sagot, 2005). Some are concerned that these agreements may leave the survivor unprotected, and are a violation of survivor's due process rights (Sagot, 2005).

India is also concerned with the traditional use of an informal, male-dominated adjudicatory system. In India, DV is often linked to issues with dowry – the property or valuables given on the occasion of marriage. Though dowry was abolished in 1961, it persists throughout India in every social stratum (Natarajan, 2005). When disputes arise over the amount given in dowry or its timeliness, village elders typically support the husband and provide few resources to the wife except advice to adjust to the situation (Natarajan, 2005). India

addressed the issue of the male-dominated adjudicatory process by creating All Women Police Units, previously referred to as WPS.

DV and US Federal law: The Violence Against Women Act

The US Federal government entered the largely state-regulated problem of DV by passing the VAWA in 1994, reauthorized in 2013 (VAWA, 2013). This bill heightened penalties for sex crimes, mandated restitution for victims, and provided for sexual abuse programs and community-based shelters (Stark, 2007). It created new federal crimes – interstate DV, and interstate violation of a protective order. It also allowed for civil remedies for victims. The controversial 2013 reauthorization expanded tribal courts' jurisdiction to hear DV cases and included protections and services for Lesbian, Gay, Bi-sexual, Transgender, and Queer (LGBTQ) persons (VAWA, 2013). VAWA's constitutionality was tested by the Supreme Court in *US v. Morrison*. While *Morrison* allowed most of the law under Congress' power to regulate interstate commerce, it ruled that the civil remedies provision was unconstitutional (US Morrison, 2000).

Civil Approach to DV

Civil liability for perpetrators of DV remains a significant issue on the state and local level, involving tort and family law, as well as decisions about child custody and issuance of restraining orders. These laws vary widely by jurisdiction, in response to how the problem of DV is framed; this section will explore some US approaches and international counterparts.

Tort

Tort remedies for harms experienced are crucial for DV survivors. DV is quite costly for survivors; some estimates suggesting DV results in over 61 million dollars a year in medical bills alone (Hart and Sussman, 2004). But DV has other, less obvious, consequences as well. Survivors are often economically dependent on batterers, and may be unable to secure adequate housing for themselves and their dependents without assistance (Hart and Sussman, 2004). The types of tort claims available to a DV survivor are dependent on the particular circumstances of the case. Torts against the person, like battery, assault, and intentional infliction of emotional distress, are possible causes of action against the batterer. In addition, there may be grounds for property claims like interference by exclusion, replevin, conversion, and destruction to property, or contract claims like fraud, interference with contractual relations, breach of fiduciary duty and others (Hart and Sussman, 2004). There are several difficulties with these intentional causes of action, however: the batterer may not have sufficient funds to pay the judgment, the insurance company may not cover DV torts, and the statute of limitations for an intentional tort is relatively short (Wriggins, 2001).

Survivors may also have claims against third parties who had a duty to intervene or protect against DV, and who failed by either act or omission. These individuals, if shown to be in a special relationship to the individual experiencing violence, are uniquely positioned and have a duty to provide care. These individuals may include law enforcement, landlords, or employers, if they had reason to know about the dangerous situation (Hart and Sussman, 2004).

Other Civil Actions

DV is also an issue in many divorce cases, and may be considered relevant when dividing property, assigning child custody, and determining spousal and child support obligations. Courts have held that a history of DV may be considered when reallocating to past temporary spousal support what had previously been distributed from a trust account for child support (In re Marriage of MacManus (2010)). The timing of divorce with tort actions creates issues of claim preclusion. Some courts have refused to hear DV tort claims following the conclusion of a no-fault divorce (Drew, 2005). Other courts have allowed later tort causes of action when not based on the same underlying issues as the divorce. The Swedish Supreme Court presumed that joint parental custody is in the best interest of the child and is preferred when courts determine child custody, either following divorce or separation of unmarried parents (NJA, 2006 s 26). DV is an exception to this general rule; if there is a history of violence in the relationship, the court may order sole custody (NJA, 2006 s 26).

DV also has an impact on bankruptcy proceedings because the costs and the claims associated with DV are varied. Domestic support obligations and unliquidated DV tort claims are nondischargeable in bankruptcy, a provision designed to protect the DV survivor from their batterer's bankruptcy filing. When the survivor is the one filing for bankruptcy, however, the US bankruptcy Code's limitations on liquidation and relief can make a relational and financial fresh start difficult (Satz and Brandt, 2007).

Remedies: Restraining Orders

Protective orders were one of the first legal remedies for DV and are now a common and widespread response to the epidemic of DV, available in every state and increasingly worldwide (Runge, 2012). They are intended as preventative measures, although they need to be enforced through fines or imprisonment. Protective orders can take a wide variety of forms: prohibiting contact, ordering counseling, limiting visitation, creating exclusive use of once-shared property, prohibiting firearm possession, and ordering the cessation of stalking (Runge, 2012).

The means of obtaining a protective order differ according to jurisdiction and situation. Protective orders in criminal cases are typically for the period while the case is ongoing, though criminal courts are increasingly given the power to issue permanent injunctions (Buzawa and Buzawa, 2003). Temporary restraining orders can be issued within days of filing a complaint and are typically *ex parte*. Permanent protective orders can be issued following a DV criminal proceeding or a hearing on a temporary order in family court. Violations of these orders carry various consequences. In some jurisdictions, violations are classified as misdemeanors, while in others the violation is the same as contempt of court (Buzawa and Buzawa, 2003).

Protective orders have some serious flaws. Involvement with the legal system may alert the batterer as to the victim's whereabouts, putting the victim at further risk (Kerrick, 2011). In addition, to be fully effective protective orders require institutional coordination and knowledge of the order's existence. In the United States, there is no database of protective orders available for field officers to check and the victim's court document may not be immediately available to the officer at the scene (Buzawa and Buzawa, 2003). Third, protective orders rely on victim initiation and pursuit, which may be challenging given the victim's state of mind and resources (Buzawa and Buzawa, 2003). Finally, the officer may not have any legal obligation to proactively enforce a protective order, as the US Supreme Court found in *Castle Rock* (*Castle Rock v. Gonzalez*).

Aligning more with the jurisprudence of the Inter-American Commission on Human Rights than the US Supreme Court, courts outside the United States have found that states do have positive obligations to protect individuals from DV. The European Court of Human Rights has used international human rights law like the Convention on the Elimination of All Forms of Discrimination against Women (CEDAW) to create positive obligations on the part of states to ensure sufficient criminal justice response to acts of DV (McQuigg, 2011). These obligations may include preventative measures on an operational level to protect individuals from criminal acts (*Osman v. United Kingdom* 87/1997/871/1083). It is unclear the extent of these positive measures when they require a state's monetary commitment, for instance in the provision of alternative housing for victims of DV (McQuigg, 2011).

One persistent issue with protective orders is enforcement beyond their jurisdictional limits. In Australia, a protective order is not automatically enforceable in each state where the survivor travels or lives. However, survivors may register their protective order to ensure its enforceability when he/she moves or takes an extended stay in another state. Interstate registration does not require notice to the respondent party, and therefore works as an additional protective measure (Protective Orders, 2012).

The European Union (EU) sought to address the jurisdictional enforcement gap through a new law for its member states. In 2013, the EU Ministers of Justice passed a Europe-wide protective order for DV survivors (European Commission Memo, 2013). It provides a guarantee that protective orders will remain enforceable throughout the EU regardless of whether the survivor leaves the issuing country. It extends the 2011 Europe-wide criminal protective order enforcement to civil protective orders (European Commission Memo, 2013). A law passed in 2012 in Turkey went one step further; it provides for electronic ankle bracelets for perpetrators and alarm mechanisms in necklaces or mobile phones for petitioners to easily alert authorities about a violation (Zeldin, 2012).

DV and International Human Rights Law

International human rights law recreates some of the challenges for DV that exist in domestic law because both are grounded in the liberal view of the autonomous legal subject (Fineman, 2010). This view of the rights-holding legal subject requires an expansive notion of individual freedoms and thus negative rights – meaning that the state remains out of private life (McQuigg, 2011). In addition, international law is drafted to hold accountable state, not private, actors, further reinforcing the public/private divide (McQuigg, 2011). Human rights law applies to state action, a framing that often excludes DV, committed in private rather than as official action of the state. This has meant lack of state responsibility, intervention, and remediation for victims. Some argue that state neutrality on violence is impossible and action is needed to avoid empowering the abuser (Copelon, 2003). Human rights law has increasingly been used to address DV under alternative theories of state action, and has created positive state obligations in response to systemic allowances for DV that fail to protect rights-holders from nonstate conduct (Hessbruegge, 2005).

Advocates have worked to extend human rights law to apply in the 'private' sphere in different ways: (1) human rights law can be enacted to apply directly against private actors, as in the South African Constitution; (2) domestic law can be drafted to protect human rights, like the antidiscrimination legislation in the UK; (3) courts can apply law in a way that protects human rights, for instance, in line with the European Convention on Human Rights; and (4) state responsibility can be construed to create a positive obligation to protect private individuals, like in the European Court of Human Rights (McQuigg, 2011). For example, after the US Supreme Court held that state law did not entitle the holder of a DV restraining order to police enforcement of that order, the Inter-American Commission on Human Rights found that the United States violated the human rights of the plaintiff by failing to act with due diligence to protect her and her daughters from DV, and violated the state's obligation to provide equal protection (IACHR Report 80/11, 2011). The Commission applied the American Declaration, which recognizes the human rights owed by Organization of American States member states to individuals (American Declaration, 1948). The focus in the remainder of this article will be on violence against women to address the widespread issue of DV.

Convention on the Elimination of all Forms of Discrimination against Women (CEDAW)

The United Nations adopted CEDAW in 1979, and it entered into force in 1981. The Convention originally mentioned 'gender based violence,' though not specifically DV; but it did emphasize equality and the "elimination of prejudices and customary and all other practices which are based on the idea of the inferiority or the superiority of either of the sexes" (Article 5). Violence against women became an explicit part of the Convention in 1992 when the Committee adopted general recommendation 19, listing specific types of DV against women (paragraphs 11, 23). The Committee specifically recommended that states take "appropriate and effective measures" against public and private acts of violence, including the full range of legal measures: "penal sanctions, civil remedies and compensatory provisions … preventative measures, [… and] protective measures" (paragraph 24). Thus states parties have a duty to protect individuals, even within the home. The 188 states

parties to CEDAW are responsible for formerly private violence, including acts and failure to act.

This seemingly wide acceptance of state responsibility to end violence against women is undercut by numerous reservations made by signatory countries (CEDAW, SP/2006/2). Some of these reservations are against core provisions of CEDAW like Article 2, which "condemns discrimination against women in all its forms," even though Article 28 expressly prohibits any reservation incompatible with the object and purpose of the Convention. These reservations keep many states parties from engaging in a revolution of gender relationships that would change the dynamics of control that lead to DV.

CEDAW is an international law that relies on exposure, shaming, and international standards to compel state action (Merry, 2003). But enforcement is possible for states parties who have ratified the optional protocol, which provides individual complaint mechanisms to the Committee (Optional Protocol A/RES/54/4, 15 October 1999). It was adopted by the UN in 1999, and ratified by some states parties to CEDAW. Even without this enforcement arm, however, the cultural and standard-setting work of CEDAW and states reports are important; both allow an international view on the social, economic, and cultural aspects of gender and violence (Merry, 2003).

Other International Laws

Beyond CEDAW, there have been other important international agreements concerning the status of violence against women. For example, the UN established a Special Rapporteur on Violence against Women in 1994 through the Commission on Human Rights, and the Human Rights Council renewed it in 2013. The 2006 report recognized that states sanction 'honor killings' against women who transgress social norms and other types of violence against women by failing to create legislation to prohibit these 'traditional practices' (Due Diligence Standard, 2006). While the due diligence standard has been used for various initiatives in the prevention, protection, and prosecution of violence, the Special Rapporteur noted that more work needs to be done in the area of reparations for victims of violence (Due Diligence Standard, 2006).

The Beijing Platform for Action addresses various issues related to women's equality, including violence, and was one of the outcomes of the Fourth Conference on Women in 1995 (Platform for Action, 1995). This platform recognizes that violence against women is a "manifestation of the historically unequal power relations between men and women," and that this violence should be addressed regardless of its location (Platform for Action, 1995). The Platform recommends steps for various stakeholders to adopt, ranging from the UN itself to various local institutions, all in the service of fulfilling the strategic goals of eliminating violence and studying its causes. In addition to promoting states' adoption of CEDAW, especially general recommendation 19, the Platform also emphasizes the importance of access to justice and effective remedies for victims of violence (Platform for Action, 1995).

While the aspirational language of these international treaties and the global goals of ending violence against women are laudable, commentators note their limitations. Some note that they take for granted a postconflict setting which creates a gap in gender justice for countries in conflict (Scully et al., 2010). Some question whether they are as effective for enforcement as various regional agreements that take into account cultural and religious heterogeneity (Faedi, 2010). This applies especially in light of countries' widespread adoption of, yet failure to enforce, human rights treaties. Regional human rights agreements can punish violations, while still respecting countries' independence and suspicions that international documents may be examples of colonial and Western interference (Faedi, 2010). In some of these countries, men's authority is perceived as natural, while women's rights will violate the community's cultural heritage. Other resistance to international human rights treaties and the aggressive criminal enforcement that they provoke come from postcolonial feminists. Some argue that these treaties focus inordinately on violence against women as wrongs to be addressed instead of a positive focus on women's rights (Kapur, 2013).

Moving Forward, Contested Language; Transcending Gendered Dimensions of domestic Violence law

The discourse surrounding DV and the law has moved from decidedly gendered to aspirationally gender-neutral. This development has been partly due to antifeminist backlash and arguments alleging a violation of equal protection (Booth Hvass, 2002). Antifeminist critics contest woman-centered laws that provide resources for battered women's shelters. Such positions have been criticized as revealing an entitlement to patriarchal privilege, and as a resistance to any definition of violence that does not reinforce patriarchy (Dragiewicz, 2011). Irrespective of this language shift, however, law and policy-making continue to emphasize crime control mechanisms instead of structural changes that would foster greater equality and liberty (Ferraro, 1996).

Legal contests over DV are a significant locus for analyzing changing social norms around gender expectations, stereotypes, and the structure of the family. (Fineman and Mykitiuk, 1994) Legal approaches to DV show a society's relative valuation of promoting nonviolence regardless of its context or location, and preserving privacy and invisibility for domestic arrangements (Dragiewicz, 2011).

Domestic Violence: Sociological Perspectives

Rebecca E Dobash and Russell P Dobash, University of Manchester, Manchester, UK

© 2015 Elsevier Ltd. All rights reserved.

Abstract

Domestic violence is characterized by a recent history of rapid social change in institutional policy and practice. The problem is primarily one of men's violence against women and a considerable proportion of women have experienced this type of physical and sexual violence. Physical injuries are often severe and women may suffer from persistent health and emotional problems. When women are murdered, the perpetrator is usually an intimate partner. Women find it difficult to leave a violent relationship because of threats, lack of support, and, historically, the inadequate responses of institutions. Sociological explanations stress the importance of male power and control.

Overview

The issue of 'domestic violence' is an important area of public, political, and academic concern that goes to the heart of the institution of the family and marriage and of gender relations between men and women. It encompasses public and private life as well as social, political, and economic institutions. At the social level, it involves ideological beliefs and institutional policies and practices. At the individual level, it involves personal attitudes and prejudices as well as individual behavior and conventions of daily life. The area is characterized by a history of recent, rapid, social change in institutional policy and practice and is steeped in controversy. There have been political, ideological, and academic controversies about the term itself, the definition of the phenomenon, the nature of the problem, research methods used in its study, findings about the nature and occurrence of the problem, and about the focus and effectiveness of social and legal interventions. Since its rediscovery in Britain and the United States in the early 1970s, virtually every aspect of this issue has been the subject of development and the object of debate not only within the academic community but also across a wide spectrum of society as the media, community activists, academic researchers, and policy makers have taken different positions and entered into sustained and sometimes heated debates. The lively nature of this important social problem warrants further examination of each of the issues touched upon within this characterization, which can only be summarized here.

Most researchers and policy makers agree that the global problem of domestic violence is primarily one of men's violence against women in intimate relationships, and that it has a long and ignoble history. Numerous studies suggest that a considerable proportion of women in a marital or maritallike relationship have experienced domestic violence, that the physical violence is usually associated with other forms of intimidation and control, and that sexual aggression is a significant aspect of many acts of nonlethal and lethal violence against women partners. Men's violence has important consequences for the women they abuse including numerous and repeated physical injuries, sometimes severe and permanent; persistent health problems; and emotional consequences. Women find it very difficult, and sometimes impossible, to leave a violent relationship because of threats of further violence, lack of economic and social support, and insufficient or inadequate responses of statutory and voluntary agencies. When women are murdered, the most likely perpetrator is a male intimate partner or expartner.

Sociological explanations of domestic violence emphasize male privilege, power, and control, and stress the importance of patriarchal beliefs and ideals and the laws, policies, and practices associated with them. Other explanations emphasize individual pathology and/or social traits such as frustration-aggression and the like. Future research will continue to concentrate on efforts to explain domestic violence and the predicament of the women who experience it, as well as issues relating to the impact of social and legal interventions relating to the safety of victims and those concerning the nature and extent of men's violence and the effectiveness of various responses to abusers.

Definition

The terms wife beating, battered wives, wife abuse, woman abuse, spouse abuse, family violence, domestic violence, and intimate partner violence have all been used to describe this phenomenon. The terms and the conceptions they reflect have all been topics of debate and have evolved over time. The initial terminology reflected the notion of husbands and wives in a legally sanctioned marital relationship but quickly evolved to include non-state sanctioned cohabiting relationships between men and women as well as same-sex intimate relationships. The various terms also reflect different conceptions of the gender of the usual perpetrators and victims of the violence: men's violence against women, mutual violence between men and women, or women's violence against men. These and other issues were the subject of considerable debate when the problem was 'rediscovered' in the 1970s and continue to be debated to the present. While the initial terms of 'wife beating' and 'wife abuse' contained a clear imagery of men's violence against a woman partner, they also contained notions of formal marriage as a necessary condition of concern and attention. By contrast, the term 'domestic violence' included the notion that the problem occurred in both state and non-state sanctioned relationships but lost the conception of gender asymmetry regarding who was most likely to be the victim and who the

perpetrate of the violence. For reasons of popular convention rather than resolution of these debates, the term 'domestic violence' became the term in common usage throughout most of the world.

History

Very ancient customs, beliefs, and laws dating back to the early Roman Empire and many of the first conventions of marriage allowed a husband to kill his wife for infidelity and serious challenges to his male authority. These 'rights' were slowly eroded over time through the development of Canon law and the gradual alteration of legal systems in Europe and Britain to punishments allowing chastisement that did not kill or maim. In 1765, Sir William Blackstone's *Commentaries on the Laws of England* noted that conventional cultural beliefs and common legal practices endorsed a man's right to use 'moderate' chastisement against his wife. Blackstone's Commentaries codified this patriarchal right and thus confirmed a husband's authority over his wife for a considerable period of time. Such ideals and legal views crossed the Atlantic with some of the pioneers who brought familiar social attitudes and legal systems to the newly forming nations of North America. While there were some departures from this position, it nonetheless constituted the normative position in many European and North American cultures for a fairly long period of time. Indeed, contemporary evidence from a wide range of societies reveals strong cultural beliefs expressing such ideals, and these are often endorsed by legal practices that illustrate direct or indirect support for 'wife beating' or, at best, weak reactions to its victims and perpetrators.

In European and North American societies, the history of challenges to and changes in social and institutional responses to the problem is punctuated by three historical periods in which domestic violence was discovered anew and obtained widespread recognition as a social problem. Recognition eventually resulted in changes in the laws regulating the institution of marriage and the family as well as developments in the responses of agencies of the state, particularly law and law enforcement, but also in economic, political, and social institutions.

In the 1870s, 1910s, and 1970s, the problem of 'wife beating' was repeatedly discovered by women in Britain and North America who were engaged in more general campaigns for changes in women's marital, economic, political, and/or social status. Within each time period, wider campaigns about changes within the family and marriage (such as, the ability of women to own their own property or to obtain a divorce for excessive cruelty – 1870s), about changes in the political status of women (the right to vote – early 1900s), about changes in the economic status of women (equal pay and equal opportunities within the job market – 1970s), and changes in social relations between men and women in general also spawned an interest in the specific issue of physical violence against women within the home, usually by intimate male partners/husbands within the context of marriage. At each of these junctures, community groups (usually although not always feminist) were formed, there were public protests, public recognition was increased, and the agencies of the state were challenged and responded with public hearings, legislation, and various new policies and practices. After the first two periods of recognition and public response, the issue was soon forgotten and marked by a return to an older, established status quo in which men maintained social, political, and economic authority over women throughout society and particularly within the institution of family and marriage where this right could be exercised legally and morally through the use of violence against women/wives for various real or perceived violations of male authority.

The third period of challenge began in the 1970s, again in Britain and the United States and, rather than being forgotten after a brief period of interest, has instead continued to expand and develop throughout much of the world. Public awareness of the issue and community and state responses to it are now global, resulting in violence against women being defined by the United Nations as an issue of human rights and social justice. At present, many, although certainly not all, societies have experienced challenges to the complacency and social and institutional tolerance that once prevailed and in many countries new laws and institutional practices have been initiated.

The Nature of the Problem, Research Methods, and Findings

Controversies about the nature of the problem itself have been intense and are intertwined in other controversies about research methods and resulting findings. The debates regarding these issues were apparent at the onset of the rediscovery process in the 1970s and have altered little since, although the amount and type of research grew at a tremendous rate in the last quarter of the twentieth century. As stated above, debates about the phenomenon itself center on whether the violence is asymmetrical in nature (men as the most usual perpetrators with women the usual victims) or symmetrical (women and men as equally violent toward one another), and they sometimes even extend to the notion that women are the most likely perpetrators of domestic violence and men the usual victims of women's violence. Debates about research methods have focused on whether one method should supersede all others in producing the 'best' or indeed the only findings of value in answering the question of 'who is violent to whom.' One camp has claimed variously that only surveys based on national probability samples produce valid and reliable findings. Research using this approach has focused on questions of the prevalence of this form of violence in the population and on the relative levels of violence of men and women. Others defend the use of a wide variety of research strategies, which include historical studies showing continuities and changes in patriarchal beliefs and institutional practices over time and ethnographic studies with an intensive focus upon cultural practices as well as the more traditional sociological approaches of victim surveys, criminal statistics, intensive interview studies, studies of strategic sites, and evaluations of new interventions. Proponents of the broad-based sociological and contextual approaches claim that such studies address more pressing and relevant questions about the problem such as 'what is the exact nature of the violence,' 'how are victims and offenders processed by agencies of the state,' and 'what

works at stopping violence.' Such investigations also attempt to examine in detail the contextual dynamics of violent episodes and violent relationships as well as the meaning and consequences of being a victim and/or perpetrator.

Some survey research, particularly in the United States, has relied primarily on a single measurement tool that counts discrete acts (e.g., a shove, a slap, a punch, or a kick) with little or no assessment of issues, such as intentions (e.g., physical harm, intimidation and fear, or retaliation of self defense), the consequences of the acts (e.g., a bruise, a cut, a burn, or a broken bone), or the contexts in which the violence occurs. Counting one shove the same as one punch or one kick appears to support the notion of symmetry in the perpetration of domestic violence, with women deemed to be equally or even more violent than their male partners. With the claim of symmetry in domestic violence comes the notions that theoretical accounts of domestic violence should be gender neutral and that gender is not related to violence within intimate relationships. By contrast, other surveys and more intensive research methods that are not based on this purely act-based measurement find the opposite pattern, that men are the most likely perpetrators and women the most likely victims of domestic violence and thus conclude that domestic violence is asymmetrical and related to gender. Predictably, these contradictory findings have resulted in considerable controversy with claims and counterclaims regarding the validity and reliability of each type of measurement and resulting skepticism regarding the veracity of findings produced by this single measurement tool.

Over time, controversy about the simple question of 'symmetry–asymmetry' – who perpetrates the majority of violent acts (men or women) – has become more complex with the addition of further research questions regarding who is most likely to be responding in self-defense, to be harmed, to live in fear, and to experience other consequences of violence as well as additional research efforts to differentiate between violent acts, threats, intimidation, verbal aggression, arguments, and the like. This evidence reveals strong and consistent patterns across cultures and historical periods showing that the problem of domestic violence is primarily one of men's violence against women that often results in injuries and sometimes ends in the death of the victimized woman and/or her children. Survey research across several countries indicates that anywhere from one-quarter to one-half of women who have lived in intimate relationships with men report at least one incident of violence, and many women report repeated violence. Across countries, anywhere from 10 to 50% of women also report sexual violence from intimate male partners ranging from forced sexual relations to rape. In addition, homicide statistics worldwide suggest that women are more at risk of being killed by a male partner than by anyone else. Every year, in Britain and North America between 40 and 50% of all women who are murdered are killed by an intimate partner or expartner. By contrast, very few men who are murdered are killed by a woman partner. Some of the risk factors associated with lethal and nonlethal domestic violence include economic and educational disadvantage, youth, and cohabiting versus marital relationships. Situational risks include high levels of conflict, jealousy, sexual possessiveness among male partners, and alcohol abuse. Risk of serious nonlethal and lethal violence is also associated with separation and women's attempts to leave violent relationships.

Institutional Policies and Practices

Early investigations of policy and institutional practices in the 1970s revealed considerable failure on the part of legal and social agencies to provide support and protection for women victims and their children as well as a reluctance to deal with male perpetrators. Recent research charts the many changes in policy, practices, and innovations aimed at ending men's violence and providing safety and security to women and children. Initial focus was on the police and the long-established practice of either ignoring domestic violence or treating it as a nuisance, not 'real' violence, and not 'real' police work. In the United States, several high-profile class actions against police departments were brought by feminist advocates on behalf of women who sought but did not receive police intervention after being beaten by their husband or male partner. These and other efforts elsewhere led to early changes within the criminal justice systems of several countries. Numerous initiatives included policies to strengthen arrest, civil protection orders, and exclusion orders as well as the introduction of dedicated domestic violence courts. Innovative sentencing and probation orders in some locations also included participation on the newly created programs for violent abusers such as those pioneered in Duluth, Minnesota, and later introduced in countries throughout the world.

For the most part, abuser programs are based on feminist principles and use a cognitive-behavioral approach incorporating the notion that attitudes and behaviors are learned and culturally based and, as such, can be modified and 'relearned' albeit with considerable effort on the part of the abuser. Some abuser programs are voluntary with men presenting themselves for a variety of personal reasons, often relating to the woman's threats to leave them, while other programs are tied to the justice system as conditions of a sentence after conviction for domestic violence. Here again, there has been considerable controversy as many women's groups running shelters for abused women object to abuser programs on the grounds that they take funding away from efforts to support abused women, that they may treat abusers with too much leniency, and in the belief that they do not work in stopping the violence. The controversy was probably at its most intense throughout the 1990s and vestiges still remain today, although most shelter groups and abuser programs now work cooperatively in the context of a coordinated community response. These include a combination of services for abused women and their children as well as various programs and criminal justice responses aimed at ending the violence of abusers.

Theoretical Accounts

Theoretical explanations of domestic violence predictably include a plethora of competing, at times contradictory, accounts, ranging from the sociocultural to the individualistic. Sociological, usually feminist, explanatory frameworks stress the historical and contemporary existence of male violence

across almost all societies and locate its perpetration within patriarchal ideals and practices, emphasizing male power and control. In these accounts, violence is seen as functional, a resource used in men's attempts to enforce and maintain their domination and control, with conflicts associated with male jealousy, household labor, and economic resources constituting the contexts of violent events. Other sociologically based gender-neutral accounts emphasize power but note that this social attribute is not skewed toward either gender – men and women possess significant amounts of power – and the symmetrical violence that occurs is an expression of such power. Variants of 'gender-neutral' explanations of domestic violence emphasize the importance of individual psychology and/or social traits that are deemed to have similar effects on the violence of men and women alike; these includes stress, frustration, socialization into (sub)cultures of violence, poor anger control, and impoverished social skills. Other-individualistic accounts emphasize the pathological personalities of violent men while still others attempt to understand the predicament and actions of women who live with violent men. Evolutionary psychology has challenged the foundations of these sociocultural and individualistic explanations and, instead, locates men's violence in a universally evolved male psyche involving male sexual proprietariness toward women. Accordingly, this evolved psyche leads men to attempt to possess and control women through various means including violence.

Sociological accounts emphasize widespread social and cultural beliefs as well as institutional policies and practices through which men are privileged in their relationships to women in general and in their relationships with intimate partners in particular. At the interpersonal level, this includes a range of intimidating and controlling acts as well as concerted actions to isolate women from family and friends. Continuous forms of intimidation and isolation make it very difficult, if not impossible, for women to seek help, although it is now clear that most women do engage in active efforts to deal with the violence. Most seek help from family and friends and many also seek assistance from various voluntary organizations such as women's shelters and agencies of the state such as social work and the police. Despite these efforts, women find it difficult to leave the violent relationship. Sociocultural explanations of women's inability to leave a violent relationship stress men's threats of further violence, women's lack of economic and social support, a moral order emphasizing women's obligations to maintain family unity, and inadequate responses of agencies of the state. Other individualistic accounts, particularly in the United States, suggest that personality disorders in women are the primary reason that they are unable to leave violent relationships. According to such accounts, women do not leave violent relationships because they suffer from conditions such as masochism, relationship addiction, 'battered woman'syndrome, and learned helplessness.

By the 1990s and into the 2000s, the enhanced and refined nature of the research questions, along with an increasing concern to evaluate the relative effectiveness of new innovations have further expanded the theoretical questions and the relevant research strategies in this area. Future research in the area will continue to concentrate on efforts to explain domestic violence within the broader social and cultural contexts in which it occurs as well as examine the behavior, motivations and intentions of the men who perpetrate this violence and the predicament of the women who experience it.

The focus on social institutions will continue to address questions about the impact and effectiveness of various social and legal interventions and innovations concerning the welfare and safety of victims and the violence of male abusers. While much of the earliest research was shaped within sociology, women's studies, history and law, the global expansion of interest in this social problem has been mirrored by an equal expansion of disciplines contributing to its study as psychology, criminology, health care, and medicine have variously contributed to advances in knowledge about this significant social problem.

Dominant Designs

Abstract

The concept of the dominant (technological) design occupies a central position in the literature on technological cycles and technological evolution, entry timing advantages, and firm performance and survival. The emergence of a dominant design constitutes a watershed moment in the evolution of technologies and associated industries, as it signals the resolution of technological uncertainty and the maturation of the industry. This is generally accompanied by a change in the nature of innovation (from product to process innovation), a shift in the locus of competition, a shakeout in the number of firms in the industry, and mass adoption on the consumer side.

The dominant design is a single architecture that establishes dominance in a product class (Abernathy, 1978; Anderson and Tushman, 1990). Its emergence is generally seen as demarcating the maturation of an industry or product class. The concept of the dominant (technological) design occupies a central position in the literature across diverse disciplines that deal with technological evolution and the organization of markets. It has been linked to shifting industry structures, to firm and product performance, to firms' entry and exit rates, to time-of-entry advantages, to shifts in innovation types, and to industrial and organizational evolution (Tushman and Murmann, 1998).

Foundations: Technology Cycles

The concept of the dominant design can be traced back to the work of Abernathy and Utterback (Utterback and Abernathy, 1975; Abernathy, 1978; Abernathy and Utterback, 1978). Studying technological evolution, their work and subsequent research have noted that such evolution is not random, but follows a cyclical pattern of variation, selection, and retention. Technological cycles start with stochastic, discontinuous technological breakthroughs that lead to a shift in the technological paradigm (Anderson and Tushman, 1990). As the new technology is initially poorly understood, such technological discontinuities initiate periods of variation (or eras of ferment), during which different producers introduce several and often incompatible variants of the breakthrough technology. The period of variation is followed by a period of selection: competing designs are evaluated (through use and often by the end users) and some might be developed further; eventually, some designs are retained and some others are dropped. This selection process culminates in the emergence of one dominant design that establishes dominance in the product class and that is copied by the majority of producers in the industry. After the emergence of a dominant design, further variation is rare in the core components of the product architecture (and generally associated with niche markets), until a new technological discontinuity occurs to render the old dominant design obsolete and restart the technology cycle.

When and How Does a Dominant Design Emerge?

While the concept of the dominant design is rather straightforward, important questions remain with regard to exactly when and how a dominant design actually emerges. In other words, when can it be concluded that a dominant design has emerged, and what mechanisms drive the selection process among competing designs?

One approach to determining a dominant design's emergence is to track competing designs' market share. When one design accounts for over 50% of new product sales or new process installations over a significant duration, it can be concluded that it has achieved dominance (Anderson and Tushman, 1990). This threshold of 50% market share and the definition of a 'significant duration' (4 years for Anderson and Tushman, 1990) can, of course, be arbitrary and case specific. They are, however, data driven, relatively easy to apply, and generally in line with notions about dominance, and have thus been used extensively.

A somewhat different approach has been followed by scholars, which sees products as nested hierarchies of subsystems and linking mechanisms (Henderson and Clark, 1990; Murmann and Frenken, 2006). Some of these subsystems and linking mechanisms are core components of the end product (e.g., the engine in an automobile) in the sense that they largely determine how the product functions and might dictate adjustments in other components and the overall product architecture. In contrast, other components are peripheral and of less critical importance; changes in them might be dictated by changes in core components but do not trigger changes in the latter. A dominant design for the end product can be said to have emerged when products converge on their core components. After this, further advances occur in peripheral components without changing or challenging the dominant design.

But what really are the mechanisms behind this convergence on one dominant design? Scale economies and network externalities have been offered as two possible explanations (Klepper, 1997). Indeed, the concurrent existence of a multitude of designs does not allow producers to reap scale benefits, whereas it creates confusion among the consumers. In contrast, the emergence of one design as dominant allows manufacturers to optimize processes, become more efficient, and have

more stable relations with suppliers, vendors, and customers (Anderson and Tushman, 1990). On the consumer side, scale in production leads to significantly lower product costs and thus prices, and reduces uncertainty and potential problems of incompatibility between designs.

Convergence on one dominant design then confers many benefits for the ecosystem that forms around an industry. This fact per se, however, does not explicate the exact mechanisms that drive selection among competing designs. If scale economies and network externalities alone suffice to drive the selection process, even small random shocks that give one design a head start can determine which design eventually dominates. Other scholars, however, have focused more on the role of agency and sociopolitical factors in this process. A dominant design can emerge from the deliberate actions of powerful actors such as a dominant producer (e.g., IBM's successful efforts to impose its chosen standard in PCs as the industry standard to be followed by the majority of other manufacturers as well), an important consumer (e.g., the government), or industry standard-setting bodies. Similarly, the dominant design can be the result of firms strategic maneuvering and forging of alliances (Cusumano et al., 1992). Highlighting the importance of such sociopolitical and institutional factors, Suarez and Utterback (1995) note that scale economies are the result rather than the driver of a dominant design's emergence.

In general, technological superiority and early market share alone appear not to be the most crucial determinants of the selection process. In the home videocassette recorder market, for example, Betamax is generally believed to have been technologically superior to VHS, yet was quickly sidelined by the latter (Cusumano et al., 1992). In fact, it is widely accepted that the design that achieves dominance is seldom the most technologically advanced one; while achieving dominance certainly requires good performance for the task at hand, social, political, and organizational dynamics appear to play an even more important role in driving the process of design selection. The problem at such early stages of a technology cycle is that the functional implications of different designs are not well known or understood, and the metrics on which performance will be evaluated are not yet well defined (Clark, 1985). Users are unclear about what the new product should accomplish and what performance trade-offs might be necessary or appropriate (for example, in early computed tomography scanners, doctors were not clear on the relative priorities of scan time, resolution, safety, and cost (Yoxen, 1987; Tushman and Rosenkopf, 1992)).

Initially, then, even the comparison of different designs is difficult, as it requires reaching consensus on the relevant dimensions to be evaluated. Negotiation is required between producers and other stakeholders, such as users and critics. Different producers might emphasize different functionalities of the new technology, depending on their background and competitive strengths. At the same time, end users also create their own understandings of the new technology that might or might not agree with producers' understandings (Clark, 1985). Users might come up with new and unforeseen uses for the product (von Hippel, 1994) or they might demand that further technological evolution take a certain path.

Negotiation is also required within producers and across different scientific disciplines. Most new technological designs involve interactions between engineers from diverse scientific backgrounds. The production of jet engines, for example, requires that aerodynamic, metallurgical, combustion, and mechanical engineers come together and agree on the key features of the new product (Tushman and Rosenkopf, 1992). Different disciplines tend to have different norms and prioritize different aspects of the new technology or different performance metrics. Rather than fully satisfying the concerns of any group of stakeholders, any new design rather amounts to a compromise that is a satisficing solution for all.

The social construction of norms and evaluation metrics has led scholars to recognize that the selection of a dominant design among competing designs is primarily a social/political process rather than one driven by technological determinism. The need to mutually agree not only on evaluation metrics, but also on trade-offs between performance, reliability, and price that affect the market penetration of any design usually cause the dominant design not to be the most technologically advanced on any metric. The design that achieves dominance is generally not customized to the needs of any specific subset of customers or other stakeholders (i.e., it does not maximize performance on any specific dimension), but rather provides a satisficing solution across most groups of stakeholders and thus facilitates mass adoption. For the same reason, the design that achieves dominance is generally not the most expensive option (a characteristic of cutting-edge options), and is reliable enough to be adopted even by users who are still not very familiar with the new technology. The dominant design thus often amounts to the best compromise among competing designs and associated interests. Rather than being a fully new design, it emerges through a synthesis of fragmented technological innovations that have been introduced in designs earlier in the technology cycle, and have already been tested, potentially modified, and evaluated by users and other stakeholders (Suarez and Utterback, 1995).

The fact that a dominant design emerges through sociopolitical/institutional dynamics rather than through a selection process of technological determinism also implies that it is not possible to know a priori which design will eventually become dominant. While important stakeholders like large manufacturers can influence the selection process and sometimes even impose their preferred design as dominant (e.g., IBM's PC), betting on any one specific design is risky for any firm, as it can easily find itself locked in a design that fails to achieve dominance and is bound to disappear.

Boundary Conditions

Although a dominant design emerges in most product classes, there are also cases where no design achieves dominance. The conditions under which this might occur have been studied primarily by industrial economists (e.g., Katz and Shapiro, 1985; Arthur, 1989). Excess momentum and insufficient friction are two such conditions under which, instead of stabilizing around a dominant design, a market experiences constant change as consumers rush to adopt newer versions of the technology, and the market share leadership of any specific design is short-lived. At the other end of the spectrum, excess inertia can lock consumers in an older technology, thus

delaying the evolutionary cycle of a new breakthrough technology and the associated dominant design, or lock them in the design that they first adopt, thus delaying the selection process and allowing multiple designs to coexist. Multiple competing designs can also coexist when network effects are weak or nonexistent, or when incompatibilities among designs do not affect consumers severely (e.g., the incompatibility of different smartphone operating systems does not inhibit calling and other modes of communication, whereas the low cost of app development facilitates their simultaneous development for multiple operating systems). They can also coexist when preferences are as different as to render a compromise on one dominant design difficult. In this case, the multiple designs that cater to the disparate needs of multiple groups of stakeholders are likely to evolve into separate, parallel markets.

Whether a dominant design emerges and the degree to which its emergence hinges upon technological factors or sociopolitical dynamics also depend on the type of the product. Technology management scholars have differentiated between nonassembled products, simple assembled products, closed systems, and open systems, which are correspondingly characterized by increased complexity in the number and type of subcomponents and linking mechanisms (Tushman and Rosenkopf, 1992). In the case of nonassembled products, the dominant design emerges predominantly from a technological logic. For products such as cement or glass, new technologies can be rather easily evaluated in terms of speed and cost. In contrast, for assembled products performance metrics are more convoluted and no design is usually overwhelmingly superior. Under such conditions of ambiguity, sociopolitical processes play a more important role in leading to a compromise on a dominant design. As complexity further increases from simple assembled products to closed systems to open systems, so does the role of sociopolitical forces in the selection of a dominant design, as more numerous and diverse stakeholders need to reach a shared understanding on the norms and the performance metrics that are to be used to evaluate the new technology.

Further Implications of the Dominant Design Concept

Technology Cycles

The emergence of a dominant design constitutes an important event in the evolutionary cycle of a technology. Just as a discontinuous innovation starts the cycle, the emergence of a dominant design marks the industry's maturation. This is accompanied by a significant shift in the nature of innovation, which becomes incremental and focused on the peripheral rather than the core components of the design. The relatively stable product design also facilitates faster innovation in terms of process and integration that aim predominantly not at changes in the product but rather in the production process, and lead to lower costs. At this stage of a technology's evolutionary cycle, rather than attempting to produce new and superior designs, firms focus on increasing the efficiency of their production methods and achieving scale economies (Murmann and Frenken, 2006).

The emergence of a single dominant design also reduces uncertainty significantly on the side of both the producers and the end users. Before a dominant design is established, firms run the risk that their investments into any specific design will be made obsolete, if that design does not become dominant. The emergence of a dominant design largely mitigates such risks and facilitates more stable and reliable relations with suppliers, distributors, and customers (Anderson and Tushman, 1990). Similarly on the customer side, the initial coexistence of multiple designs can create confusion, whereas the risk of being locked into a design that becomes peripheral can hinder adoption especially when switching costs are high, network effects are strong, and complementary products are important. The emergence of a dominant design resolves these problems and facilitates mass adoption that leads to a takeoff in industry sales (Agarwal and Bayus, 2002).

Dominant Design and Entry Timing Advantages

Timing-of-entry and its effects on firm performance and survival occupy a central position across diverse disciplines such as industrial economics, strategy, and organizational theory. Early work on the topic focused predominantly on the advantages of early entry (Lieberman and Montgomery, 1988). Subsequent scholarship has highlighted more the significant risks that are also associated with very early entry (Lieberman and Montgomery, 1998). Bringing both these lines of research together, Christensen et al. (1998) proposed that entry during a window of opportunity that occurs right before the emergence of a dominant design maximizes firms' survival chances.

Defining the ending point of the opportunity window as coinciding with the emergence of a dominant design is relatively straightforward. The dominant design signals the maturation of the industry and shifts the locus of competition from product innovation to cost efficiency and scale economies. Firms that enter after the dominant design has emerged are seriously handicapped vs larger incumbents and thus suffer from permanently higher failure rates. Such scale advantages are less pronounced before the emergence of a dominant design as investments in process optimization only make sense after the process of design selection has concluded. However, firms that enter too early have to deal with heightened technological uncertainty and risk investing in designs that fail to become dominant. As such technological uncertainty is gradually resolved culminating in the emergence of a dominant design, firms can maximize their survival chances when they enter just prior to the dominant design's emergence and thus optimally balance reduced uncertainty with the chance to develop scale and know-how in preparation for the mature stage of the industry.

The exact consequences of and remedies for choosing the wrong design early on have been debated by scholars. Consensus generally exists that sticking to a failing design can lead a firm to fail as well or at best become a peripheral player. Switching from a failing design to the dominant one is possible (Tegarden et al., 1999), but can be risky as it often requires investment in design-specific production capacity and capabilities. Another option for early entrants is that they invest concurrently in multiple designs. This allows them to increase

the probability of guessing correctly the eventual dominant design and gaining an early foothold in it, and can also make them more flexible and faster to change course, if their initial guesses are proven wrong (Sorenson, 2000). In either case, the fact that a dominant design can only be known *post facto* creates significant challenges for early entrants who have been found to suffer from permanently higher failure rates in comparison to firms that enter during the window of opportunity that occurs just prior to the dominant design's emergence and when more concrete information is available on which design will emerge triumphant.

Social, Cognitive, and Political Factors in Technology Evolution

Even though the importance of social, cognitive, and political factors in influencing technological evolution has been recognized even in the very early research on the matter, few scholars had studied these factors in detail (an early exception is Clark, 1985). Some recent studies have attempted to fill in this gap. In their recent study of the digital camera industry, for example, Benner and Tripsas (2012) use the notion of frames to study the origin of technological designs in new industries. As they find, a producers' background and prior experience bear significant influence on how they understand the new industry and what kind of designs they introduce. Under conditions of heightened uncertainty as are those characterizing a new industry, actors use analogies in an attempt to frame the new and unfamiliar in terms of the old and familiar. Thus, even though discontinuous innovation leads to a shift in the technological paradigm (Dosi and Nelson, 2013), the new paradigm is not free from influences emanating from the old one. Resemblance to older and familiar artifacts can also influence how users understand the new product and how willing they are to adopt any particular design (Bingham and Kahl, 2013), thus also influencing the design selection process and the choice of the dominant design.

In a similar vein, Suarez et al. (2014) borrow heavily from work in organizational theory to propose that technological evolution is accompanied by a concurrent categorical evolution. In an attempt to understand and interpret the new technology, stakeholders develop categories that group together products that are perceived to be similar. The notions of similarity and difference essentially hinge upon the socially/politically negotiated dimensions or features that are considered salient for evaluating and categorizing competing designs. Being sociocognitive constructs, different categories capture different understandings or visions of the emerging industry and roughly correspond to different designs. Closely following technological designs, categories go through a similar cycle of variation, selection, and retention that culminates in the emergence of a dominant category, the conceptual schema that most stakeholders adhere to when referring to products that address similar needs and compete for the same market space. The emergence of the dominant category resolves sociocognitive uncertainty in the industry, just as the emergence of the dominant design resolves technological uncertainty. Together, the two concepts define the starting and ending points correspondingly of the window of opportunity for firm entry to emerging industries.

Limitations and Critique

While particularly important for understanding the process of technological innovation and technology cycles, the concept of the dominant design also has some limitations. The most important among them is probably the fact that in most cases the emergence of a dominant design can only be assessed *post facto*. This inability to anticipate which design will dominate offers little guidance to firms. Even though literature on the matter makes it clear that entry to an industry after the emergence of a dominant design is problematic, it does not offer many tools for earlier entrants that need to navigate the uncertainty that is prevalent before the dominant design is established. Such early entrants, then, seem to have two options other than just betting blindly on any one design. First, they can try to impose their chosen design as dominant through deliberate actions that aim at influencing the selection process. Such strategic maneuvering generally requires building mutualistic coalitions or ecosystems around the chosen design in order to give it adequate momentum (Cusumano et al., 1992; Wade, 1995). This is, however, a risky option. Even designs that are technologically superior and supported by large and powerful corporations can fail to achieve dominance, as vividly demonstrated by the case of Sony's Betamax (Cusumano et al., 1992). Firms that invest heavily in and commit to a specific design that fails to achieve dominance face a significant risk to fail as well, especially when they are relatively small in size and cannot afford a repositioning. Alternatively, firms can hedge their bets by investing in multiple designs at the same time. Rather than being fully committed to any specific design, these firms can test the waters, acquire valuable firsthand knowledge about consumer preferences, and develop skills that will allow them to change course quickly if necessary and adopt the dominant design as soon as it emerges. Firms that follow this strategy can have lower failure rates (Sorenson, 2000), but usually also do not aspire to influence the industry's evolution or become market leaders.

In a similar fashion, while the emergence of a dominant design is a useful marker for the closing of the opportunity window for firm entry, it offers little guidance with regard to the opening or the duration of the window and the optimal time for entry. Christensen et al. (1998) in their study of the disk drive industry considered the window to open 3 years before the emergence of the dominant design. However, this was an empirical and ad hoc approach that cannot be generalized across research settings. In fact, if the dominant design can only be assessed *post facto*, the same necessarily will hold for the window of opportunity, thus offering very little concrete information to potential entrants about the optimal entry timing. The concept of the dominant category (Suarez et al., 2014) might offer some more guidance with regard to the assessment of the window of opportunity, yet research on the matter is still at its very early stages.

Conclusions

Since its inception nearly in 1975 (Utterback and Abernathy, 1975), the concept of the dominant design has occupied a central position in research on technological evolution,

timing-of-entry advantages, and organizational performance. Scholarship in these lines of research has been rich and fruitful, advancing significantly the understanding of technological innovation and evolution, and of the role of discontinuous innovation, uncertainty, timing, and strategy in influencing firms' performance in new industries. The clarity of the dominant design concept as a theoretical construct has not necessarily been matched by equal ease in devising generalizable methods for studying its implications in empirical settings or in studying in depth the social, cognitive, and political drivers of design selection. The fact that this remains a vibrant field of research appears to imply that much more remains to be unearthed in this domain in order to complete the understanding of how technologies come to be and how they influence but are also influenced by their environment. Such more in-depth understanding of the technological evolutionary process will also allow scholars to offer more concrete advice to firms regarding their innovation efforts and strategies, the optimal allocation of resources, and their choice of entry timing.

Dowries and Other Marital Transfers

Abstract

Payments between families at the time of marriage existed during the history of most developed countries and are currently pervasive in many areas of the developing world. These payments can be substantial enough to affect the welfare of women and a society's distribution of wealth. The prevalence and magnitude of marriage payments vary across countries and depend upon economic conditions, societal structures, institutions, and family characteristics. Marriage payments also evolve within societies and over time. Transfers can rise sharply, and property rights over such payments can shift between marrying partners and parental generations.

Most societies, at some point in their history, have been characterized by payments at the time of marriage. Such payments typically go hand-in-hand with marriages arranged by the parents of the respective spouses. Marital transfers come in various forms and sizes but can be classified into two broad categories: transfers from the family of the bride to that of the groom, broadly termed 'dowry,' or from the groom's side to the bride's, broadly termed 'brideprice.' Brideprice occurs in two-thirds of societies recorded in Murdock's (1967) *World Ethnographic Atlas* of 1167 preindustrial societies. Conversely, dowry occurs in less than 4% of this sample. However, in terms of population numbers, dowry has played a more significant role, because the convention of dowry has occurred mainly in Europe and Asia, where more than 70% of the world's population resides.

Prevalence of Brideprice

The custom of brideprice dates back to the ancient civilizations of Egyptians, Mesopotamians, Hebrews, Aztecs, and Incas (Quale, 1988). A valid marriage contract in Islamic law required a form of brideprice (Bianquis, 1996). Classical China required the negotiation of a brideprice for the validity of marriage, and these transfers continue to be the norm in many rural areas today (Ebrey, 1993). Brideprices are currently most prevalent in Africa; more than 90% of sub-Saharan societies typically make such marriage payments (Murdock, 1967; Goody, 1973).

Prevalence of Dowry

The dowry system dates back at least to the Greeks and Romans. In medieval western Europe and later, dowries were common practice among most social and economic groups. Dowry payments were prevalent in seventeenth and eighteenth century Mexico and Brazil, where Spanish and Portuguese family law governed colonial marriages until those countries gained their independence (Nazzari, 1991; Lavrin and Couturier, 1979). In contemporary times, dowry is an almost universal phenomenon in India. In other parts of South Asia such as Bangladesh, Pakistan, and Sri Lanka, paying a dowry at the time of marriage is increasingly common.

Social Characteristics and the Occurrence of Marriage Payments

There are certain characteristics that distinguish between those societies where the burden of marriage payments falls primarily on the groom's family and brideprices are paid and those where the bulk of the transfer comes from the bride's family and dowries are paid. The general pattern seems to be that brideprice exists more frequently in primitive, tribal, and often nomadic societies. By contrast, dowry often marks a transition to more complex societal structures. In many ancient cultures, the practice of brideprice began to wane and a transformation to the custom of dowry occurred as these civilizations grew and flourished. Goody's (1973) sample of 857 preindustrial societies and Murdock's (1967) sample of 1167 societies also confirms that dowry is mainly found in societies exhibiting substantial socioeconomic differentiation and class stratification. In present times, this pattern is reflected in a comparison between dowry-paying India, where the caste system represents perhaps an extreme example of social stratification, and the more homogeneous tribal societies of sub-Saharan Africa that practice brideprice.

Although brideprice is typically associated with reduced social stratification, societies which do practice the custom are typically developed enough to own some form of property to transfer at the time of marriage. In contrast, in many of the indigenous cultures of North and South America, which seem to have been characterized by more propertyless subsistence, marriage payments were relatively rare (Schlegel and Eloul, 1988).

Brideprice-paying societies have also been associated with a strong female role in agriculture. Boserup (1970), in particular, has argued that brideprice is found in societies in which agriculture relies on light tools (such as the hoe), and thus where women are actively engaged. In contrast, Boserup argues dowry is more common in heavy plow agriculture where the role for women is limited.

The use of brideprice has tended to correlate with polygyny (men have more than one wife) and also with the possibility

 http://dx.doi.org/10.1016/B978-0-08-097086-8.31099-6

of divorce. In contrast, monogamy is the norm and divorce is rare in dowry-paying societies. Lineage and locality of post-marital residence seem to play little role in determining the direction of payments. Both dowry- and brideprice-paying societies tend to be patrilineal (children belong to the lineage of their father) and patrilocal (brides join the household of grooms and their families upon marriage) (Goody, 1973; Murdock, 1967; Quale, 1988).

Family Characteristics as Determinants of Marriage Payments

Determinants of Brideprices

Because women generally join the household of their groom at the time of marriage, brideprice is typically considered to be the payment a husband owes to a bride's parents for the right to her labor and reproductive capabilities. The amount of brideprice required has usually been rather uniform throughout the society, where the size is linked directly to the number of rights that are transferred, and not to the wealth level of the families involved (Quale, 1988; Goody, 1973). Brideprice amounts typically also do not vary with the rank of the wife in polygynous marriages.

Ancient brideprice was often considered a direct payment for a bride's virginity. Where marriage to paternal cousins is common, the brideprice is often higher if the bride married a more distant relative because, in that case, the groom gained rights to a woman and children from a more distant lineage (Bianquis, 1996). The amount of brideprice can also depend on the expected number of children a woman will bear. For example, a divorced woman who already has children will receive a lower brideprice, whereas women who reach puberty earlier receive a higher price (Dekker and Hoogeveen, 2002; Mulder, 1995).

In sub-Saharan Africa, a central purpose of the brideprice is to create an alliance between kinship groups (Dekker and Hoogeveen, 2002; Ekong, 1992). As a result, raising the brideprice is often the responsibility of the groom's extended lineage group, with the principle contributions coming from his father, grandfather, and father's brothers, and with mother's brothers making small contributions. Likewise, since in this setting the entire lineage group has rights to a woman, the brideprice is distributed among many members of the bride's extended family. In this case, larger brideprices can arise with larger lineage groups.

Determinants of Dowries

Relative to brideprices, the amount of dowry varies substantially and tends to be negotiated on an individual basis. Dowry typically arises in complex socioeconomic, non-kinship-based societies, with endogamous marriage practices; that is, where men and women from families of equal social status marry. Dowry then becomes a means to maintain social status by attracting a husband of at least equal standing for one's daughter. It correlates with strongly class-based social systems where higher-level individuals – by virtue of wealth, power, and possibly claim to a superior hereditary status – do not willingly intermarry with the lower levels. A high-status husband might mean a Brahmin in India, or an aristocrat in Renaissance Europe, but the forces tending toward the use of dowry are the same. As a result, the amount of dowry generally increases not only with the wealth of the bride's father, but also with groom's future prospects.

Historically, there is a positive relationship between the amount of dowry transferred and both sides' household wealth. For modern India, dowries are largest among the highest ranking castes (Rao, 1993; Dalmia and Lawrence, 2005). Strikingly similar preferences seem to determine dowry payments in current-day South Asia and in historical Europe. According to Chojancki (2000), the Renaissance marriage market valued maturity in grooms, chaste youth in brides, and family wealth and prominence for both. Typically, in India, the most important quality of a bride is a good appearance, whereas for a groom it is the ability to earn a living, often reflected in his educational level (Caldwell et al., 1983; Billig, 1992). In South Asia today, dowry levels increase with the education of grooms (Dalmia and Lawrence, 2005).

Property Rights and Marriage Payments

Marriage payments not only differ by on whom the financial burden falls (either the grooms' brideprice or the brides' dowry), but also ownership rights to these transfers can vary and evolve through time. Payments from the groom's side are either transferred directly to the brides' parents, formally termed 'brideprice,' or to the bride directly, commonly known as 'dower.' Similarly, payments from the bride's parents can either go to the bride herself, referred to as 'dowry,' or be directly transferred to the groom and his family, termed 'groomprice,' to the exclusion of the bride. Both dowry (as a pre-mortem inheritance) and dower are transfers that remain with the conjugal couple but are the formal property of the wife throughout the marriage.

Brideprice and Property Rights

Brideprice transfers, where the bride's parents receive the payment, are the norm in sub-Saharan Africa. Dower, which remains the property of the bride and is usually considered her insurance in case of divorce or husband's death, is most typical of traditional Islamic marriages. The historical record on brideprice versus dower suggests property rights over the marriage transfer evolve through time.

Within the ancient civilizations of the Babylonians, Egyptians, and Hebrews, there was an overall shift away from brideprice to dowry as the society developed and urbanized. An additional feature of this transformation was that the marriage payment seemed to change first from a brideprice to a dower and then finally to a dowry (Quale, 1988). A similar transformation seemed to occur for the Germanic tribes of the early Middle Ages (Hughes, 1985). By the fifth century, the Burgundians awarded one-third of their brideprice to their wives and two-thirds to their wives' kinsmen. By the time the law codes were issued, the Visigoths seem to have totally incorporated their ancient brideprice into the award grooms made to their brides. This pattern is also reflected in the traditional Chinese practice of transferring a brideprice directly to the

bride's parents, who then return a portion of this as dowry to their daughter. This amount is kept by the daughter as personal property throughout the marriage.

Dowry and Property Rights

Ownership rights over marriage payments from the brides' side have also undergone transformations. Most commonly, the traditional dowry transfer is considered to be a 'pre-mortem inheritance' to the daughter, which formally remains her property throughout the marriage. Goody (1973), in particular, has emphasized this role of dowry in systems of 'diverging devolution,' where both sons and daughters have inheritance rights to their parent's property. As Botticini and Siow (2003) summarize, a strong link exists between women's rights to inherit property and the receipt of a dowry. This is seen in ancient Rome, medieval western Europe, and the Byzantine Empire.

In numerous historical instances, dowry as bequests has given way to groomprices – a direct transfer to grooms. Chojancki (2000) documents the emergence of a gift of cash to the groom (*corredo*) as a component of marriage payments in Renaissance Venice. Krishner (1991) confirms a pattern of legislation across northern and central Italy granting husbands broader control over wife's dowry assets beginning in the fourteenth century. Common law, in which dowry came under immediate control of husbands, predominated in England during the sixteenth and seventeenth centuries (Erickson, 1993). All of these examples point to a time of increased commercial activity and societal inequality, where groomprices emerged to secure husbands from prominent families.

Nowhere, however, has this transformation been more dramatic than in present-day India over the last few decades. The traditional custom of *stridhan*, a parental gift to the bride, has changed into modern-day groomprices that have a highly contractual and obligatory nature (Caldwell et al., 1983; Billig, 1992). Generally a bride is unable to marry without providing such a payment. This transition in marriage payments happened at a time of significant structural change, as unprecedented opportunities for economic and political mobility began to open up following India's independence in 1947. Several studies connect the emergence of groomprice to competition among brides for more desirable grooms (Srinivas, 1984). This transformation into groomprice is occurring elsewhere in South Asia, too. The Pakistan Law Commission reviewed dowry legislation in 1993 adding a new sub-clause stating grooms should be prohibited from demanding a dowry. In Bangladesh, a clear distinction remains between the traditional dowry, *joutuk*, gifts from the bride's family to the bride, and the new groom payments referred to as *demand*, which emerged post-Independence in the 1970s (Amin and Cain, 1995).

Rising Marriage Payments

In many contexts, marriage payments have risen substantially. Such rises occur particularly for dowries, and have often precipitated legislative and regulatory initiatives to reduce their effect. Real dowries have recently been rising in India, where payments now can amount to as much as six times the annual income of bridal parents. The political outcry against this escalation of dowry payments culminated in the passage of the Dowry Prohibition Act in 1961 outlawing the practice. But despite this law, dowry inflation has persisted unabated. Similar legislation has occurred in Pakistan and Bangladesh. Dowry inflation is also well documented to have occurred in historical Europe. For example, the scale of dowry demands in Florence led to the establishment of the Florentine Dowry Fund in 1424, which was designed to alleviate the government's fiscal problems while providing families with a government-secured investment for accumulating dowries (Molho, 1994).

The demographic explanation for dowry inflation considers the relative supply of grooms and brides in the marriage market. In most societies, men on average, marry younger women. Since women reach marriageable age ahead of men, increases in population could affect the numbers of potential brides first, thus effectively causing an excess supply of potential brides in the marriage market. If grooms are in relatively short supply, a corresponding increase in the price of husbands should occur, and hence a rise in dowries. The flip side of an excess supply of grooms would consequently lead to brideprice inflation. Some anthropological research on brideprice inflation in colonial Africa has indeed made the link between higher brideprices and greater demand for wives leading to increased out-migration of eligible grooms (Wilson, 1981).

Marriage Payments and the Welfare of Women

Although marriage payments can take many different forms, no consensus exists on which of these forms, if any, will enhance the welfare of women. In theory, brideprice could be interpreted as explicit recognition and valuing of women's productivity and contribution to marriage; in practice, it often serves to limit women's control over their bodies. Both sexually and in terms of their labor, brideprice has long been linked to domestic violence, owing to women's fear of returning to their natal home without being able to repay the brideprice (Ansell, 2001). African women's rights campaigners advocate the abolishment of the practice, and have linked it to the spread of AIDS, since brideprice as payment for sexual rights leads to women's loss of say in sexual protection and frequency (Wendo, 2004).

In theory, dowry, as a pre-mortem inheritance, is set up to protect property given to women. However, this institution often seems to have been transformed into giving these property rights to men. Early feminists in Europe attacked the dowry system precisely because they objected to the fact that husbands ended up controlling the funds (Cox, 1995). An even more significant factor is the magnitude of these payments. In current-day South Asia, dowry payments can impoverish the bridal family, and dramatically affect the lives of unmarried women, who are increasingly considered burdensome economic liabilities. The custom of dowry in India has been linked to female infanticide and, among married women, to 'bride-burning' and 'dowry-death' – physical harm inflicted on the wife (sometimes leading to death) to extract promised dowry payments (Bloch and Rao, 2002). The National Crime Bureau of the Government of India reports approximately

8000 to 9000 dowry deaths every year. Numerous incidents of dowry-related violence are never reported; Menski (1998) estimates the number as roughly 25 000 per year. Other estimates point to as many as 100 000 per year (Anderson and Ray, 2012).

Abstract

Drawing on the language of the theater, dramaturgical analysis illuminates how people derive shared understandings and collaboratively construct reality in everyday, cultural, organizational, and institutional life. Dramaturgical analysis centers on two interrelated concepts: the stage or region and the social roles enacted or performed in each region. Several academic fields contribute to and are enhanced by the approach including sociology, communication studies, anthropology, psychology, social psychology, political science, philosophy, linguistics, psychotherapy, cultural studies, performance studies, film studies, and the methods of narrative and qualitative analysis. Following an overview of earlier conceptualizations and contemporary applications, a summary of critiques and defenses of dramaturgical analysis is presented. The article concludes with a note on the challenges and opportunities dramaturgical analysts face in the rapidly changing digital age.

Dramaturgical analysis of social interaction is based on the assumption that social acts are 'staged', consciously or unconsciously, and thus embody all the elements found in enactments in the theater. Some dramaturgists, especially those following Goffman (1959), assert that life is like theater. From this perspective, "social life can be understood as a series of performances" (Brissett and Edgley, 1990: p. 36). Applying the theater metaphor and various theatrical concepts turns the analytic spotlight on how people collaboratively perform and manage social roles in their everyday life encounters. Other dramaturgists, especially those following Burke's (1968, 1969) 'dramatism', contend that life is a theater (Branaman, 2013). Rejecting dramaturgy as the application of 'a mere metaphor', proponents of this approach contend that the theater reflects life itself. In other words, plays on the theater stage highlight all the elements of ordinary social life to present to an audience a new perspective on some aspect of social interaction. Thus, concepts used in theater production can be turned back again for the analysis of the social behavior that they are designed to reflect.

Regardless of the scholar's ontological position concerning the relationship between the theater and everyday life, dramaturgical analysis illuminates how people construct reality (Berger and Luckmann, 1966) and sustain the interaction order (Goffman, 1983). As Edgley notes in *The Drama of Social Life: A Dramaturgical Handbook*, "stripped to its essentials, dramaturgy is about the ways in which human beings, in concert with similarly situated others, create meaning in their lives" (2013: p. 2). The shared overall meaning, the definition of the situation, binds the participants in any situation or encounter together. The meaning may take the form of an image, a theme, a plot, or a script.

The Main Concepts

Dramaturgical analysis centers on two interrelated concepts: the stage or action area region and on the social roles enacted or performed in each region (Hare and Blumberg, 1988). In *The Presentation of Everyday Life*, Goffman (1959) identified three action area regions – backstage, frontstage, and offstage. The backstage area is where the actors prepare for their roles and where special effects are produced to influence the audience. Frontstage is where the action takes place in full view of the audience.

For any action area, there may also be offstage areas in which persons who have organized the activity (producers), as well as those who have rehearsed the cast (directors) and are providing cues for action, remain hidden from the audience. In addition, there may be a person or group who provided the original idea or script for the performance (playwright). This does not complete the list as there may also be persons who cater for the audience.

The region affects the actor's ability to control information to which the audience is privy and consequently the capacity to sustain a credible performance. If the audience were able to get a glimpse backstage, the impressions the actors are seeking to foster frontstage could be discredited. For example, a peek behind the swinging doors of an expensive restaurant revealing the chaotic and intense activities of chefs, waitpersons, and dishwashers would likely yield a quite different impression than the calm elegance being staged in the dining area. For some activities or performances such as street demonstrations (Martin, 2013), the segregation of stages and thus the capacity to shield the audience from discrediting information or impressions that are discrepant from the roles the performers are playing can be difficult. The advent of digital technologies (e.g., the Internet, social media, e-mail, cell phones, and surveillance cameras) and thus virtual space as a performance region provides both new opportunities and new challenges for actors seeking to control information intentionally 'given' and that which is unwittingly 'given off' (Goffman, 1959; Gottschalk and Whitmer, 2013; Markham, 2013).

In face-to-face interaction as well as in some mediated venues, people take turns serving in the roles of performer and audience for each other even in situations in which two people are involved in the interaction. When one is speaking,

[†] Deceased.

 http://dx.doi.org/10.1016/B978-0-08-097086-8.32046-3

the other is listening. As an audience, an actor provides consensual reality, cueing, social reinforcement, and continual observation (Sarbin in Allen and Scheibe, 1982). In the progression of the development of social interaction over time, agreement on an actable idea and scripting consistent with the overall meaning constitutes the first phase. The second phase involves staging by locating or constructing an action area and providing resources such as props, costumes, and other necessary equipment. In the third phase, which may overlap with the second, actors are recruited, if they are not already involved in the development of the actable idea, and the actors are trained for their roles. The fourth phase is the period of enactment when the play is performed. In the final phase, after the performance, new meanings for selves, others, and the situation may be interpreted or assessed by the actors and audience.

The actable ideas that form the basis for social dramas may be either very general or very specific in their implications. On one end of the continuum is an actable idea in the form of an image, an emotionally loaded set of words, physical object, or event, for example, 9/11 or 'terrorist threat' (Altheide, 2013). An image has a program of action packed into it much like a symbol in a dream may be a merger of waking events. An image often guides interaction in a small informal or therapy group. The actable idea may be a more complex theme (including a direction of movement, an emotional tone, and a minimal set of roles to be enacted) or a plot (with a detailed scenario, defined roles, and an indication of the phases a group must go through to reach its goal). At the specific end of the continuum, the idea may be as fully developed as a script for a play, with parts for each member of the cast and stage directions to guide the performance. A script is most evident in organizations, especially where the actors must use equipment.

Building on the perspective of Burke (1969), Duncan (1968) emphasizes the importance of symbols, especially as they reflect authority relationships. For MacCannell and MacCannell (1982), the study of signs and symbols had become so important by the late 1900s that they suggested a semiotic interpretation of modern culture as an approach to the time of the sign. Brissett and Edgley (2006) add to the list variables that follow from the work of Goffman (1959) with a primary focus on the way in which individuals present themselves to others. These variables include role distance, the case when an individual is playing a role with full consciousness and thereby has the choice of either modifying the role or ceasing to play it altogether (Goffman, 1961; Stebbins, 2013); ecstasy, stepping outside the world of everyday life; and remedial work, when a person attempts to change the meaning of an act from one that is seen as offensive to one that is acceptable.

Academic Fields That Contribute to Dramaturgical Analysis

Dramaturgical analysis has been used in several ways. The first way, employed primarily by sociologists within the symbolic interactionist tradition, focuses on role playing (Goffman, 1959) in a wide variety of studies regarding cultural, organizational, and political life (Manning, 2004). The second way, introduced by the philosopher–linguist Burke (1969), and utilized most frequently by communication scholars, is based on the analysis of the act (Branaman, 2013). Another approach, used primarily by anthropologists, is to analyze the function of social dramas that are enacted by the members of a society to bring about conflict resolution (Turner, 1974), to signify a rite of passage, or to memorialize some important event in the history of the society (Drummond, 2013).

Since role and script are central concepts for drama, the fields of psychology, social psychology, political science, philosophy, linguistics, psychotherapy, cultural studies, performance studies, film studies, and the methods of narrative and qualitative analysis, also include descriptions of similar relationships that can be incorporated in the dramaturgical perspective.

Earlier Conceptualizations of the Dramaturgical Perspective

The fundamental idea of people playing roles for audiences who take those performances into consideration and adjust their subsequent lines of action has been around for several centuries. Evreinoff, in *The Theatre in Life* (1927), records that, at least since the sixteenth century, the similarity between life and theater has been noted by Shakespeare and others. However, the dramaturgical perspective was not widely used until it was popularized by Goffman in the 1960s. The 1930–35 edition of the *Encyclopedia of the Social Sciences*, edited by Seligman and Johnson, does not include an entry on the dramaturgical perspective, although there is an entry for drama, covering activity in theaters. Burke's entry on dramatism in the 1968 *International Encyclopedia of the Social Sciences*, edited by Sills, presents Burke's pentad of the five terms: act, scene, agent, agency, and purpose. Sets of concepts are linked in ratios, such as the scene–act ratio, where the scene (the situation) has implicit in it the attitudes and behaviors that will become explicit through action. Burke places his own work clearly in the symbolic interaction tradition with references to Mead (1938).

Brissett and Edgley, in various editions (1973, 1990, and 2006) of their source book on *Life as Theater*, emphasize that dramaturgy is the study of how human beings accomplish meaning in their lives through interaction with others. For them "meaning is a continually problematic accomplishment of human interaction and it is fraught with change, novelty, and ambiguity" (1990: p. 2). Edgley asserts that "the simplicity of the dramaturgical principle—that the meaning of people's conduct is to be found in the manner in which they express themselves in interaction with similarly expressive others belies the scope and power of the perspective" (2013: p. 2). Just as meaning is created and expressed through enaction, it can be recreated through reenaction. Moreno, observing that "every second time is a liberation from the first" (Hare and Hare, 1996), developed psychodrama as a method of group therapy based on reenactment.

In the 1992 *Encyclopedia of Sociology* edited by Borgatta and Borgatta in the entry on 'Dramaturgy,' Warner records that the unique insight of dramaturgy is that daily social interaction consists of performances that individuals stage and in which they present themselves to others. As with Brissett and Edgley (2006), the emphasis is on the work of Goffman and the symbolic interaction tradition of Mead and the Chicago School. Curiously, the 2000 edition of the *Encyclopedia of Sociology* edited by Borgatta and Montgomery lacks an entry on the topic of dramaturgy.

Contemporary Applications of Dramaturgical Analysis

Over a half century since Goffman popularized dramaturgical analysis, the approach continues to stimulate and shape scholarly research and theorizing across a plethora of disciplines and substantive areas. Early empirical research guided by the dramaturgical perspective examined a variety of institutional and organizational realms including funerals (Turner and Edgley, 1976), political impression management (Hall, 1979), idiosyncrasy credit earned by new religious movements (Snow, 1979), celebratory crowds (Snow et al., 1981), prisoners' presentations of self (Watson, 1982), the feeling rules and emotion work of flight attendants and bill collectors (Hochschild, 1983), and the social construction and communication of power by social movements (Benford and Hunt, 1992) to name but a few. Edgley's (2013) volume reflects the sustained contemporary influence of and interest in dramaturgy. The 19 original papers in that collection are equally divided between conceptual elaborations and empirical investigations of topics including social movements and dramatic framing (Benford, 2013), police/protester interaction and political impression management (Martin, 2013), media dramas fanning public fears concerning domestic terrorism (Altheide, 2013), the performative body and body impression management (Waskul and Vannini, 2013), museum dramas (vom Lehn, 2013), the staging of emotions by barbershop quartets (Nash, 2013), transsexuals' gendered identity work (Sumerau et al., 2013), sadomasochistic play (Newmahr, 2013), dramaturgy in online encounters (Gottschalk and Whitmer, 2013), and symboling in the drama of human evolution (Halton, 2013). Taken together, these studies indicate that dramaturgical analysis remains a vibrant approach for the social sciences, illuminating a variety of domains in everyday, cultural, organizational, and institutional life.

Critiques and Defenses of Dramaturgical Analysis

Brissett and Edgley (1990, 2006), Edgley (2013), and Manning (2004) provide lists of various criticisms that have been leveled at dramaturgy. For some critics, dramaturgy is a pedestrian, nonsystematic form of inquiry that does not possess the properties of formal theory. Brissett and Edgley agree that for those who would prefer a linear sequential analysis of human behavior and who wish to employ dramaturgy to test hypotheses, the lack of formal propositions is a shortcoming. But they go on to suggest that dramaturgy's theoretical elasticity is also one of its strengths:

> In fact, we believe it is precisely because dramaturgy is not a closed theoretical position, but rather a way of describing human behavior, that it is such an informative and heuristic mode of thought. (Brissett and Edgley, 1990: p. 24)

They also note that dramaturgy is linked propositionally to other forms of social thought, such as symbolic interactionism, ethnomethodology, existential sociology, interpersonal psychology, and various humanistic models in the social sciences. Edgley further deflects this criticism by pointing out that "dramaturgy is a tool, a perspective, and a point of view, not a paradigm" (2013: p. 8).

The second criticism is that dramaturgy does not produce universal statements about human behavior. It is said to be an artifact of studying the situational behavior in Western culture. In response, Brissett and Edgley (1990) first noted that understanding how people interact in the Western society is no small achievement, but go on to point to the fact that the expressive behavior of individuals is well documented in the anthropological literature outside the Western world.

Dramaturgy, or at least Goffman's version of it, has also been criticized for its methodology. It is said to lack a systematic method of testing propositions about the world. Hunt and Benford (1997: p. 106) agree that a "systematic rendering of a dramaturgical methodology has not been attempted." They outlined a qualitative dramaturgical methodology for studying collective action and social movements; but their blueprint would not satisfy those wishing to apply quantitative techniques to studying such phenomena. Brissett and Edgley (1990) responded to critics that there is nothing special about doing dramaturgy. Being sensitive to the expressive dimension of behavior demands no special methodology or observational skills. However, there should be an unnerving and single-minded commitment to the observation of people's doings.

The fourth criticism is that dramaturgy slights the impact of larger social units, such as institutions, on human behavior. In response, Brissett and Edgley (1990) assert that there can be no doubt that people's interaction contexts are circumscribed by structural arrangements. However, rather than dwelling on the limitations, dramaturgy focuses on what people actually do within the contexts that are available to them. Edgley elaborates:

> The preoccupations of macro-sociologists are but mere background to dramaturgists for whom the action on stage is primary in every way. Background matters may influence, pressure, encourage, or condition, but in the last analysis they do not determine the course of interaction in whose crucible novelty and surprise are always possible. (2013: p. 3)

Moreover, dramaturgy's central concept of role is used as a way of accounting for people's connections to one another as well as to the structures and organizations with which they are identified.

Several scholars have criticized the dramaturgical perspective for its implicitly jaded view of human nature portraying people as self-interested manipulators, con-artists, liars, and other disingenuous characters. Edgley responds that such critics have failed to take into account the simple distinction that "human beings are not only expressive, but often aware of their expressiveness". He elaborates:

> To these critics, the dramaturgical image of human beings as expressive creatures who are also aware of their expressiveness means that they are persons constantly concerned with manipulating that awareness in order to influence how others see them. Possibilities become probabilities and probabilities become certainties. So if people *could* have self-serving interests in mind when acting on their dramaturgical awareness, then this is proof-positive that they *do*… But simply because people *might* have nefarious motives for exercising dramaturgical awareness doesn't mean that they *do*. Not all presentations are misrepresentations… (Edgley, 2013: p. 7)

Edgley further suggests that some of the critics are also selling our species short as well as underestimating the scope of dramaturgical analysis. "Con games, deceit, cynicism and treachery are all dramaturgically accomplished to be sure", he concedes; "but love, truth, sincerity, and authenticity are as well" (p. 7).

Finally, the most prevalent critique has to do with the theatrical metaphor. Critics say that the theater is make-believe and everyday life is real. Brissett and Edgley (1990) respond that life is neither theater nor is it different from theater. It is theaterlike. They recommend that dramaturgy and social science more generally drop all claims to ontology because

> …all knowledge of and about social life is necessarily interpretive. As symbolic creatures, we have the capacity to interpret and express our observations…but our knowledge is limited by the symbols at our disposal. While there may indeed be a "real" world out there, to claim that any particular theory or model reflects, captures, or perceives the world, is quite another matter. (p. 34)

They suggest that social scientists would be well advised to follow Gamson's recommendation to "abandon the bewildering issue of what is reality and substitute the more manageable question: Under what circumstances do we think things are real?" (1975: p. 603).

Future Directions for Theory and Research

The rapidly changing digital landscape provides new challenges and opportunities for dramaturgical analyses. The sheer volume of communications and interactions being spewed out in nearly every sphere of private and public social life means there are innumerable new venues in which performers and audiences are constructing meanings, interpreting, and reacting to each other's messages and impressions. Researchers employing a dramaturgical approach to studying digitally mediated encounters and interactions will find it necessary to develop new methodologies to keep pace with the implications of these technological innovations. As Gottschalk and Whitmer observe, "Since what happens online does not stay online, we must constantly resolve the tensions between the infinity of interactional opportunities our online life provides us, and the offline consequences of enjoying them" (2013: p. 328). For performers, the digital world presents new challenges to controlling information and the audiences who gain access to the performances. Thus, there are more opportunities to have one's impressions discredited by the unintentional or intentional release of discrepant information. Dramaturgical analysts will have unlimited data at their fingertips, which further illuminate the dynamics and fragility of everyday life. And they will need to confront new ethical dilemmas as private and public selves become more blurred in the digital age.

Abstract

Recent neuroimaging, neuroanatomical, neurophysiological, pharmacological, and dream content analysis studies have shed new light on the neural underpinnings of dreaming. In this article, we review converging evidence from these distinct lines of research suggesting that the generation of dreams primarily relies on the activation of brain networks implicated in memory, emotional and reward processes, as well as parieto-occipital regions, related to sensory and visuospatial imagery. We show that these activations may account for distinct characteristics of dream reports from non-rapid eye movement sleep (NREM) and rapid eye movement sleep (REM). Compared to NREM dreams, REM dreams are more perceptually vivid, and more emotional, including 'avoidance' (e.g., avoiding a danger or a threat through fleeing, freezing, or hiding) and approach-like behaviors (e.g., behaviors of exploration and quest for something rewarding, interesting, appetitive, or sexual). In addition, several frontal and parietal regions implicated in executive and attentional functions during wakefulness are significantly deactivated during REM sleep, explaining the disorientation, lack of insight, and impaired working memory typical of REM dreaming. Based on these new data, recent theoretical proposals suggest that dreaming fulfills important functions pertaining to emotion regulation and memory. However, support for the role of dreaming in waking performance is scarce, and more research is needed that would integrate dream content analysis with an assessment of emotion and memory functions. More generally, we suggest that studies combining measurements of brain activity and of concomitant mental activity (dream reports) will provide new insights into the neural determinants of dreaming and thus illuminate an essential facet of human consciousness.

Introduction

Humans have always been intrigued by the nature and varieties of dream experiences. Indeed, the main phenomenological characteristics of the dreams are highly consistent across individuals, including some of the most bizarre dream features. Because they differ or often aberrate from waking experiences, dreams were initially believed to carry messages coming from outside of the individual (from divinities and other spiritual entities) and played a central role in the mythologies of human cultures. In the history of dream research, the first major scientific endeavor to investigate dreaming from a neurological and phenomenological perspective took place during the second half of the nineteenth century. Dreams were not only considered as providing reliable descriptions of what can be perceived, felt, or thought by the dreamer, but also as an essential source of information about the brain processes at work during sleep (Noreika and Windt, 2008; Schwartz, 2000). For example, in his book on sleep and dreaming, Alfred Maury (1862) from the College of France postulated that, contrary to what happens during the waking state, the different parts of the dreaming brain are not synchronized anymore: "perception, memory, imagination, will, judgment are unevenly developed during dreams, indicating different degrees of activity in certain parts of the cerebral hemispheres" (1862, p. 35, our translation). Accordingly, studying dreams would provide unique insights into the varieties of cognitive functions and their underlying neural organization, because of their momentary dissociation during sleep. This period of dream research was characterized by detailed introspective observations, questionnaire studies, and ingenuous experimentation (Lavie and Hobson, 1986; Schwartz, 2000). However, early in the twentieth century, experimental dream research became either dismissed by behaviorist principles (Hillner, 1984) or supplanted

by Freud's psychoanalytical conception of dreams as representing interpretable but disguised fulfillments of repressed wishes, originating from an unconscious mind (Freud, 1900). Note that no systematic empirical evidence supports that dreams result from the transformation of disturbing thoughts, wishes, or fears into symbols that would then need to be decoded. Recent findings instead converge to suggest that dreams and their peculiarities may be considered as relatively unequivocal manifestations of mental and neurobiological processes occurring during sleep. In particular, and as we show below, emotionally relevant memories and concerns, which are highly prevalent in dreams, may be prioritized for reprocessing during sleep. Current predominant models of dreaming therefore reconnect with the late nineteenth-century view that sensory, cognitive, and emotional experiences in dreams, as well as their typical bizarre features, may help specify what type of information is processed by the sleeping brain and how (Schwartz, 2000).

During the second half of the twentieth century, substantial progress in the understanding of the neurophysiology of sleep was made and provided an objective foundation for the scientific study of dreaming (Desseilles et al., 2011; Hobson, 1988; Schwartz and Maquet, 2002). More recently, thanks to the development of advanced neuroimaging techniques yielding measures of regional brain activity during sleep, the study of the relationship between brain function during sleep and dream phenomenology has emerged as an attractive topic of research (Dresler et al., 2011; Horikawa et al., 2013; Schwartz and Maquet, 2002). However, because dreams are introspective descriptions of first-person experiences, linking brain activity to subjectivity is a common staple but uncompleted and difficult task for both empirical dream research and consciousness studies.

Below, we first describe the phenomenological characteristics of the dreaming experience. We then show how distinct cognitive and emotional dimensions in dreams may relate to specific underlying neural correlates, as these are derived from neuroimaging, neuroanatomical, neurophysiological, and pharmacological studies. Based on these findings, we then discuss about the generation and possible functions of dreaming.

Definition and Phenomenology of Dreaming

Existing definitions of dreaming range from 'any mental activity occurring in sleep' to more specific definitions in terms of formed, multimodal hallucinations, strong emotions, and distinctive cognitive features (Pagel et al., 2001; Windt, 2010). In this article, we use a relatively broad definition of dreaming as corresponding to any internally generated sensory, motor, emotional, or cognitive subjective experiences that occur during sleep. As a first-person experience, dreaming is accessible through introspection and is usually reported during the awake state through memory recall. Dream reports may therefore be influenced by several factors such as forgetting, reconstruction mechanisms, verbal description difficulties, censorship, experimental demands, and lack of independent verification. Using appropriate strategies, it is possible to minimize the impact of these factors on dream recall (see Schwartz and Maquet, 2002).

In the 1950s, Nathaniel Kleitman, Eugene Aserinsky, and William Dement first showed that sleep was periodically interrupted by activation of the electroencephalogram (EEG), associated with bursts of rapid eye movement sleep (REM) and increased dream recall (Aserinsky and Kleitman, 1953; Dement and Kleitman, 1957). From then on, dreaming was considered to occur exclusively during the so-called REM sleep stage, and this 'REM = dreaming' equation predominated the field of dream research, despite some early disclaimers (Foulkes, 1962). However, over the past 10 years, this view evolved considerably with accumulating evidence showing that dreaming can occur during REM and non-REM (NREM) sleep (Oudiette et al., 2012). Some phenomenological characteristics may differentiate REM from NREM dreams. In particular, NREM dreams appear generally more thought-like, including real-life concerns, with less aggressive and friendlier interactions of the dreamer with its environment, and seem to involve self-referential processes (McNamara et al., 2005). By contrast, REM dream reports are characterized by vivid imagery, increased and often negative emotionality (e.g., fear, anxiety, anger), behaviors with high motivational value (e.g., sexual interactions), and bizarre, altered, or implausible (compared to waking life) situations (Schredl, 2010). Note however that these global characteristics of dreaming vary over the course of the night, with NREM dreams becoming progressively longer, less thought-like, and more dreamlike and bizarre, thus resembling REM dreams toward the end of the night (Fosse et al., 2004).

Neural Correlates of Dreaming

Neuroimaging Studies

Recent brain imaging methods have provided unprecedented insights into human brain functions, including regional activity during sleep. Yet, scientists face several problems when attempting to interpret neuroimaging data of sleep because of the difficulty in collecting concomitant behavioral measures (Schwartz, 2013). In this context, dream reports represent a major source of information about how cognitive and emotional processes may operate during sleep (Schwartz and Maquet, 2002). Of course, this proposal assumes that dream reports offer reliable and accurate descriptions of sensory, emotional, and cognitive experiences during sleep. Thus, typical features of dream experiences, such as vivid visual imagery, reactivation of memories, emotional intensification, bizarreness, illusion of reality, etc., may inform about underlying brain circuits activated during sleep. Conversely, patterns of activity during sleep provide converging support for the implication of specific brain networks in the generation of dreams (Hobson et al., 2000; Schwartz and Maquet, 2002; Schwartz, 2004). The reciprocal relationship between specific phenomenological characteristics in the dreams and patterns of brain activation during sleep presupposes that the neurophysiological mechanisms underlying cognitive and emotional functions are the same across wake and sleep states. This hypothesis is supported by a recent neuroimaging study in which lucid dreamers activated sensorimotor cortex whenever they signaled that they dreamed of hand movements (Dresler et al., 2011). Moreover, another neuroimaging study showed

that patterns of brain activity recorded while sleeping subjects experienced specific mental images (e.g., categories of objects, scenes, and people) are similar to those elicited by the perception of corresponding visual stimuli during the awake state, and demonstrated that it is therefore possible to predict the contents of visual imagery during sleep based on measured brain activity (Horikawa et al., 2013). Below we provide an overview of the main findings from recent neuroimaging studies of sleep.

Early brain imaging studies reported that, compared to the awake state, NREM sleep was generally characterized by decreases in brain activity across multiple and distributed brain structures (Maquet et al., 1997). Recent studies revealed that transient and strong increases in regional brain activity also occurred during the different stages of NREM sleep. Specifically, during the transition from wakefulness to light sleep (stage N1), bilateral increases in regional glucose metabolism have been observed in the ventral striatum, anterior cingulate cortex (ACC), and the medial temporal lobe, including the amygdala and hippocampus (Nofzinger et al., 2002). Sleep stage N2 is characterized by bursts of oscillatory activity seen on the EEG recording and called sleep spindles. Sleep spindles have been associated with neural plasticity (Diekelmann and Born, 2010). During sleep spindles, brain activity is increased in the thalamus, and in emotion- and memory-related regions such as the ACC, insula, the medial prefrontal cortex (mPFC), and hippocampus (Schabus et al., 2007). Sleep stage N3 is characterized by slow oscillations which have been associated with activity increases in the brain stem, ventral prefrontal cortex, parahippocampal gyrus, precuneus, and posterior cingulate cortex. Thus, each slow oscillation may restore brief wakelike activity patterns (Dang-Vu et al., 2008). Increased activity observed during sleep spindles and slow oscillations occurs in brain areas known to be involved in memory consolidation, consistent with the idea that NREM sleep may promote memory processing. Functional connectivity studies also demonstrated that core subsystems of the brain's 'default network,' typically activated during daydreaming and autobiographical memory retrieval (Buckner et al., 2008), are activated during N1 and N2 sleep stages (Horovitz et al., 2008; Larson-Prior et al., 2009; Laufs et al., 2007), while connectivity with frontal regions is selectively altered particularly during deeper sleep stages (Horovitz et al., 2009; Samann et al., 2011). These stage-dependent changes in the connectivity within the default network may favor the expression of self-reflection, social skills, and 'mentalizing', during NREM sleep, although consciousness might be generally reduced during deep sleep. Electrophysiological recordings during NREM sleep in rodents have documented a spontaneous reactivation (or replay) of neuronal firing patterns in the ventral striatum and hippocampus, which seems to foster the off-line linkage of memory traces with a motivational value (Lansink et al., 2008; Pennartz et al., 2004). Taken together, these studies suggest that brain regions involved in memory replay, motivation, and self-referential processing are activated during NREM sleep, and explain some typical features of NREM dreaming such as the frequent incorporation of current concerns from real-life and self-related thoughts.

On the other hand, regions activated during REM sleep in humans are consistent with some main characteristics of the dreaming experience, usually associated with this sleep stage (**Figure 1**). A first set of activated regions consists in the thalamus, basal forebrain, as well as in limbic and paralimbic structures, including bilateral amygdala, hippocampus, mPFC, and ACC (Braun et al., 1997; Maquet et al., 1996; Nofzinger et al., 1997). Activation of the amygdala may reflect intense emotions, in particular fear, anxiety, and aggressiveness, often experienced in dreams. Amygdala, mPFC, and ACC activity could also subserve emotion regulation processes (e.g., extinction of fear, Hauner et al., 2013; Kleim et al., 2013). Activation of limbic and paralimbic regions suggests that the REM state could favor the reactivation and processing of emotionally salient memories. This pattern of activation would also promote the incorporation of recent memories in dreams, which is commonly observed in dream studies. Other activated regions comprise associative sensory regions and the parieto–temporo–occipital (PTO) junction which could contribute to the generation of sensory and spatial imagery in dreams. Finally, activation of motor circuits is consistent with dreamed motor actions (Braun et al., 1997; Dresler et al., 2011). By contrast, when compared to wakefulness, several regions implicated in executive and attentional functions during wakefulness are significantly deactivated during REM sleep, including the dorsolateral prefrontal cortex, orbitofrontal cortex, posterior cingulate gyrus, precuneus, and the inferior parietal cortex (Braun et al., 1997; Maquet et al., 1996). Reduced activity in these regions may explain the disorientation, lack of insight, illogical thinking, and poor working memory found in REM dreaming. **Figure 1** shows the main anatomical regions whose activity is modified during REM sleep and their plausible contribution to distinctive features in REM dreams.

Lately, a few studies looked at EEG measures preceding awakenings with and without dream recall. The results showed that changes in cortical oscillatory activity may predict successful dream recall: whenever cortical activity was more 'REM-like,' dream recall was more likely after both NREM and REM sleep (Chellappa et al., 2011; Marzano et al., 2011).

This nonexhaustive selection of studies demonstrates that brain imaging methods can be used to investigate the neural substrates of mental processes occurring during sleep. Conversely, future studies are expected to show that dream characteristics may represent biomarkers of important brain functions, such as emotional regulation processes (Desseilles et al., 2011). Thus, research in the domain of sleep in health and disease would benefit from collecting dreams in a systematic manner.

Neuroanatomical Studies

The implication of the functional neuroimaging studies for our understanding of the neural bases of dreaming is limited by the difficulty of obtaining detailed concomitant dream data. In this context, lesion studies (along with pharmacological studies) offer increased specificity regarding the contribution of selective brain regions to distinct dream characteristics. In 1997, Mark Solms established a first classification of dream disorders based on a large study that included 361 neurological and neurosurgical patients (Solms, 1997). Approximately one-third of these patients reported

Figure 1 (a) Functional neuroanatomy of REM sleep. Brain regions more activated during REM sleep are shown in red and less activated in blue. Abbreviations: dlPFC: dorsolateral prefrontal cortex; mPFC: medial prefrontal cortex; REM: rapid eye movement sleep; VTA: ventral tegmental area. (b) The specific pattern of cerebral activation/deactivation may explain and be correlated with specific phenomenological characteristics of dreams pertaining to memory, reward and emotional processing, attentional control, visual imagery, delusional beliefs, and mentalizing.

a global cessation of dreaming subsequent to the brain damage, which predominantly involved damage to the PTO junction. Lesion in the PTO region may impact visual imagery and spatial cognition, thus suggesting that these cognitive abilities are necessary for the generation of dreams. Cessation of dreaming was also observed in a few patients with lesions in the white matter surrounding the frontal horns of the lateral ventricles, which can disrupt the connections from the ventral tegmental area (VTA) to the ventral striatum, amygdala, hippocampus, and frontal cortex. These regions form the mesolimbic circuit of the SEEKING system, which is a basic psychobehavioral emotional and motivational system of the mammalian brain, related to approach behaviors and to the feeling of anticipation while seeking a reward (Panksepp, 1998). Note that these lesions do not alter REM sleep, suggesting that REM sleep might not be mandatory for dreaming; instead dreaming would require the activation of the dopamine-driven SEEKING system (Solms, 2000). We should keep in mind that such lesions do not only alter dopaminergic, but also cholinergic and noradrenergic efferent and afferent connections.

Modern brain imaging methods also allow to investigate the neuroanatomy of the intact dreaming brain as well. It is indeed possible to assess the relationships between anatomical measures (e.g., regional volume, mean diffusivity) and quantitative or qualitative measures in dreams. Using this approach, De Gennaro et al. (2011) demonstrated that emotional load and dream length correlated with measures of amygdala microstructural integrity, consistent with the hypothesis that limbic regions may contribute to both the generation of dreams and their emotional content. This methodological strategy, in which brain imaging data are combined with dream data from the same individuals, appears very promising and may significantly improve our knowledge of the neural bases of dreaming.

Neurophysiological and Pharmacological Studies

Recent neurophysiological studies in rodents have provided evidence for the activation of the mesolimbic dopaminergic system during NREM and REM sleep (Dahan et al., 2007; Pennartz et al., 2004; Perogamvros and Schwartz, 2012). More specifically, bursting activity of the VTA, which is the core projecting structure of the reward and the SEEKING systems, is elevated during REM sleep, up to levels observed during waking behaviors, such as feeding, punishment, or sex (Dahan et al., 2007). Besides, it has been also shown that extracellular levels of dopamine in the nucleus accumbens (NAcc)

significantly increase during REM sleep (Lena et al., 2005). In humans, reward-related regions are also activated during REM sleep (Maquet et al., 1996). In addition, the hippocampus exhibits a theta rhythm during REM sleep in both animal and human studies (Cantero et al., 2003; Popa et al., 2010), although human theta activity may be slower and more sporadic compared to the theta in rodents (Clemens et al., 2009). This finding is interesting because increased theta oscillatory activity has been associated with novelty-seeking, exploratory and instinctual behaviors, as overtly expressed in parasomnias. Moreover, orexin neurons in the lateral hypothalamus, which contribute to motivated behaviors and emotional processing, have occasional burst discharges during REM sleep (Takahashi et al., 2008).

Several drugs can induce vivid dreams or nightmares after their administration (e.g., dopaminergic agents, amphetamines, beta-receptor blockers, cholinesterase inhibitors) (Thompson and Pierce, 1999). By contrast, the administration of dopamine antagonists is associated with a reduction in vivid dreaming and nightmares (David et al., 2004; Gaillard and Moneme, 1977; Jakovljevic et al., 2003; Lambert, 2006). Among the several possible mechanisms of pharmacologically induced dreaming, increased dopamine activity seems to be the most frequently involved. Note however that the influence of dopamine agonists or antagonists on dreaming may also be partly mediated by a modulation of REM sleep states (Hobson and Pace-Schott, 1999).

The Generation and Maintenance of Dreams

Activation of memory, reward, and emotional networks, as described above, may contribute to the memory and emotional functions of sleep (Sterpenich et al., 2007; Stickgold, 2005). This claim is further supported by studies showing the deleterious consequences of insomnia and chronic sleep loss on cognitive and emotional functioning (Perogamvros et al., 2013). Conversely, dreams implicate the reactivation of motor, cognitive, or affective memories during sleep (Nielsen and Levin, 2007; Wamsley et al., 2010). Extended afferent projections from the hippocampus, which stores recent memories, to the mesolimbic system would thus result in the activation of the reward and emotional components of the reward system and generate dreaming. Extended mesolimbic reward system activation during REM sleep could explain why this stage is considered as a dream facilitator. Similarly the reactivation of memories during NREM sleep (amygdala, ACC, hippocampus, ventral striatum) would contribute to NREM dreaming. While the exact conditions for a memory trace to facilitate the production of a dream remain unknown, activation of memories with a high emotional and motivational relevance for the individual are plausibly associated with an amplified activation of the dopaminergic system during sleep.

Further support for a role of the mesolimbic dopaminergic system in dreaming comes from dream content analysis studies. For example, 'approach' behaviors in dreams (e.g., behaviors of exploration, curiosity, or engagement) may be as frequent as 'avoidance' behaviors (e.g., avoiding something through fleeing, freezing, or hiding) (Malcolm-Smith et al., 2012). Because approach is a behavior typically mediated by reward-related brain circuits, these observations in dreams thus corroborate the hypothesis that reward-seeking mechanisms are activated during sleep. Importantly, the common occurrence of approach behaviors is not incompatible with the high prevalence of negative affect in dreams (Revonsuo, 2000), because approach/avoidance behaviors and positive/negative emotions are independent psychological entities that engage partially dissociated brain circuits (respectively mesolimbic dopaminergic system and amygdala-limbic system), which are both activated during sleep.

Conclusion and Future Perspectives

Evidence has recently accumulated to show that both NREM and REM sleep contribute to important neurological and psychological processes such as memory consolidation, brain plasticity, emotional regulation, theory of mind, and creativity (Diekelmann and Born, 2010; Perogamvros et al., 2013; Stickgold and Walker, 2013). Moreover, the reprocessing of motivationally and emotionally relevant information during sleep, as demonstrated by both dream content analysis and neurophysiological studies, is consistent with the activation of reward and emotional networks during both NREM and REM sleep. Yet, although it is tempting to relate dreaming to such cognitive, emotional, or other psychological and neurological functions occurring during sleep, whether the subjective experience of dreaming is required or contributes to any of these functions remains mostly speculative. Dream consciousness may offer a neurobehavioral substrate for off-line reprocessing of emotions and for associative learning, thus influencing the development and maintenance of waking consciousness, and improving cognitive and emotional functions during wakefulness (Hobson, 2009; Perogamvros and Schwartz, 2012; Revonsuo, 2000). However, to date, support for the hypothesis of a role of dreaming in waking performance is scarce (Cartwright et al., 1998; Wamsley et al., 2010). Thus, more studies are needed that combine dream content analysis with an assessment of emotion and memory functions, before any strong conclusion can be drawn.

Summary

Current models of dreaming suggest that dreaming can occur during all sleep stages and that it is not exclusively confined to REM sleep. In this article, we review converging evidence from neuroimaging, neuroanatomical, neurophysiological, pharmacological, and dream content analysis studies suggesting that the generation of dreams primarily relies on the activation of limbic/paralimbic brain networks implicated in memory, emotional, and reward processes, as well as parieto-occipital regions related to sensory and visuospatial imagery. Moreover, reduced activity in lateral frontal and inferior parietal regions during REM sleep may explain the disorientation, lack of insight, illogical thinking, and poor working memory found in REM dreams. The distinctive phenomenological features of NREM and REM dreaming are therefore consistent with the patterns of regional brain activation and deactivation observed during sleep. Studies combining measurements of

brain activity and of concomitant mental activity (dream reports) offer a promising avenue for understanding the neural determinants of dreaming, and will thus illuminate an essential facet of human consciousness.

Abstract

The anthropology of drinking has approached alcohol and drinking in two main ways: as aspects of social health problems, and as part of acceptable, mainstream social behavior. This article examines these approaches in three periods: 1930–60, 1960–90, and 1990 to the present. Today, anthropologists increasingly focus on alcohol and drinking as social and political processes related to culture and identity within local, national, and global contexts.

Over the last century, the study of alcohol and drinking has waxed and waned as a central focus of anthropological research and writing. Drinking, which herein denotes the practices, acts, meanings, and materials related to the ingestion of ethanol (ethyl alcohol, C_2H_5OH), has been approached in anthropology in two main ways: as a social or physical problem or disease, and as a normal or normative practice shared by various members of social majorities and minorities. As anthropology has developed, however, while most other social sciences have concentrated on alcohol and drinking as they figure in social, psychological, and health problems, anthropology has increasingly tended to approach drinking as part of acceptable, mainstream behavior. In the decades prior to the twenty-first century, anthropologists contributed intensively to debates on the benefits of theorizing the drinking of alcohol as a social problem (Heath, 1987a; Hunt and Barker, 2001). In the last two decades, this debate has receded as the anthropology of drinking has converged with growing scholarly interest in culture, identity, consumption, and globalization.

Early Approaches, 1930–60

Anthropologists have studied alcohol and drinking since the beginnings of modern anthropology. Some early writing and research by anthropologists were in response to more general scholarly calls for data from non-Western societies (Glover, 1932; Bunzel, 1940; Horton, 1943; Johansson, 2001). However, as Horton (1943) showed in his examination of anthropological evidence of drinking in 'primitive' societies, there were few early systematic descriptions of ordinary drinking by anthropologists (Johansson, 2001: 3846). Before 1960 few field research projects by anthropologists had drinking as a central focus. In that period, ethnographers mainly paid attention to drinking and alcohol because both were important to the people with whom anthropologists lived and studied. Ethnographers recognized that at least a modest attention to drinking provided a useful tool with which to identify the connections among other important beliefs and behaviors in social and cultural life (Heath, 1987a: 102). It has also been apparent to field ethnographers from the start that drinking is often extremely important in methodological terms because of its roles in the sociality of researchers and hosts, and because drinking often plays an integral and integrative role in many cultures, in much that is important in public life (Kearney, 1970). Ethnographers often get information, and achieve access to wider networks and some measure of trust, through drinking with hosts, and it is often true that drinking facilitates an anthropologist's ability to navigate new social and political fields (Hansen, 1976).

Drinking is not just a methodological tool to field researchers. Today's reflexive turn in ethnographic writing has elicited many more ethnographers' stories of their own personal strengths, weaknesses, needs, and wants in a field research situation (Wilson, 2005b). The upshot of more writing by anthropologists about anthropologists has led to much more discussion of ethnographic practices, including more considerations of trust, confidence, and friendship between ethnographers and their respondents. The importance of drink and other drugs in many of these relationships and encounters is often clear. Ethnographers share drink in public and in more intimate spaces. They participate in ritual and other celebratory events, and sometimes use alcohol as gifts and inducements. Ethnographers also drink for many of the same reasons as their hosts: to enhance relaxation and laughter, to foster friendship and camaraderie, and to express some of the ethnographers' own notions of the self (Wilson, 2005a).

However, despite various references to drinking in a range of anthropological publications, and sporadic acknowledgment of the ubiquitous nature of drinking in anthropological research, alcohol and its attendant behaviors took a backseat to other matters of method and theory in anthropology before and just after World War II.

Transformations, 1960–90

The anthropology of drinking matured in the period between 1960 and the mid- to late 1980s, after which transformations in ethnographic writing and research began to subvert many theories and methods that had been central to anthropology for some time. The post–World War II boom in anthropological research, writing, and teaching produced a wealth of ethnographic studies in economic, political, and symbolic anthropology. These studies were drawn from theoretical approaches that had been gaining in influence since the 1940s, such as structuralism, psychological anthropology, ethnoscience, symbolic anthropology, cultural materialism, and political

economy. By the 1960s, anthropologists were not only making major contributions to specific areas of research on alcohol and drinking outside of anthropology, they were also producing important critiques and syntheses in the history and current state of affairs in the anthropology of drinking (as seen in Mandelbaum, 1965; MacAndrew and Edgerton, 1969; Everett et al., 1976; Heath, 1976). While much of this comparative work addressed the issues of drinking and disease, just as much addressed issues that may be represented by MacAndrew and Edgerton's (1969) consideration of 'drunken comportment.' This approach related drinking behavior and its associated effects to social norms and values, giving them equal weight to the biological impact of drinking.

In this period of transformation, a new balance in anthropological approaches to drinking was struck. Ethnographers began to complement their cross-cultural and biological studies of drinking, excessive drinking, and its effects on individual and group health, with studies of normal, normative, and moderate drinking (Heath, 1987a: 113). This new attention to various roles of drinking within various contexts of culture was due to the increasing awareness among anthropologists of the complex ways in which alcohol and drinking figured in the formal practices that had long been the focus of ethnographers. But ethnographers were now also just as interested in how alcohol and drinking figured in ordinary and everyday life, and in particular how they worked within the webs of significance, which had lately taken center stage in anthropological theorizing. In fact, this change in emphasis in the anthropology of drinking, from studies of alcoholism and alcoholics to those of drinking in everyday life, led inexorably to considerations of many aspects of drinking culture that are the mainstay of anthropology today. These studies viewed alcohol as a commodity, as a social and cultural icon, and as a symbol of group membership. They focused on drinking rituals and other practices related to drinking alcohol, but also sought to tie drinking to many other important aspects of social life, especially those that motivated people beyond the formal roles prescribed by social status and structure. This new attention in the anthropology of drinking formed part of a new wave in what was called 'symbolic anthropology.'

These transformations in theoretical approach reflected changes in anthropological definitions of research populations and the new awareness in anthropology of the importance of economics, politics, and history in the evaluation of society and culture (in a period when 'political,' 'economic,' and 'historical' anthropology were also born). In the 1960s and 1970s, anthropologists moved steadily away from consideration of the primitive to examinations of peasants, proletarians, towns, cities, class, ethnicity, race, and gender. As the complexities of modernization and development increasingly involved anthropologists, former appreciations of relatively autonomous village communities gave way to more nuanced accounts of part-societies, caught up in world forces of historical and contemporary capitalism. And within all of these theoretical interests, anthropologists began to see drinking as a practice worthy of research in its own right.

This new interest was expressed in two mutually inclusive ways. One was in the production of compendia with short case studies or with more synthetic comparative analyses of alcohol, drinking, and culture (Marshall, 1979a). The other was in full-blown ethnographic texts that had drinking as a central focus (as may be seen, for example, in Marshall, 1979b). Drinking was being consistently related to places, spaces, occasions, and many other components of everyday work and leisure, with friends, family, coworkers, and even strangers, at home and in public venues. The focus was no longer only or even principally on non-Western or 'primitive' societies, as may be seen in anthropology's turn to investigating American middle-class life, in, for example, the way in which drinking marks out the temporal and spatial transition from workplace to home (Gusfield, 1987). The specialized places set aside for drinking, such as pubs, were also new sites for anthropological investigation, which in the main showed that these places were nodes within wider social, political, and economic spaces, which crosscut many types and functions of community (Hunt and Satterlee, 1986a,b). The social context to drinking was the cement that held this new anthropology of drinking together, but this focus did not lose sight of the social problems caused by drinking, or of the minority social groups that formed around drinking practices (Spradley, 1970). Central to these new anthropological studies of drinking was the realization that the rules regarding drinking in most if not all cultures involved particularly emotional relations, which often became highly charged, leaving few people indifferent to the many roles in society to which drinking contributed (Heath, 1976).

These transformations in anthropological theory, practice, writing, and profession are perhaps best seen in relation to the publication of a landmark book in the anthropology of drinking, namely Mary Douglas's edited volume, *Constructive Drinking* (1987b). This book, in its introduction by the editor and in its contributors' essays, transcends many of the major shifts that the field of anthropology was undergoing at the time. It linked past theoretical approaches in social and cultural anthropology, such as structural functionalism and structuralism, that were then coming under increasing criticism by younger scholars, to the critiques of ethnography and ethnographic writing that themselves had been born within what had heretofore been called symbolic anthropology. In marrying these old and new approaches, in a seamless way, the book helped to achieve some of the seismic shifts in anthropology that reframed the anthropology of drinking. It helped to situate consumption, identity, and identification squarely within new forms of anthropological inquiry, and to make the anthropology of drinking, if only for a short spell, a cutting edge of anthropology.

In her introduction to the book Douglas (1987a), she reviews the main differences between most anthropologists' accounts of drinking and those of other social scientists. She showed that anthropological data reveal that in most cultures, which regularly imbibe alcohol, and that is in fact most cultures worldwide, regular and repetitive drinking is not necessarily construed as drunkenness or alcoholism. In most cases these actions are not perceived by societal members as indicative of social malfunction, but on the contrary are often signs of strong and supportive cultural relations and values (Douglas, 1987a: 4). Her overarching point was that definitions of drunkenness are culturally framed, and are relative to other practices and values in that culture. Moreover, she went on to show, in conclusions that have influenced much later

anthropological attention to drinking, that most cultures recognize drinking as social acts, which are valued and regularly performed in recognized social contexts. In these persuasive terms, she argued that drinking is a practice of social inclusion and exclusion, marking the boundaries of personal and group identities (Douglas, 1987a: 8–12).

Drinking is thus a principal practice in the social construction of the world as it is and as it should be. At the heart of this approach is the simple notion that for many people in many societies drinking is a benign action, a valued if not socially necessary aspect of formal and informal life. While this does not negate the deleterious effects of alcohol use on the health of individuals and groups who abuse the practice, it does redirect anthropological attention to how alcohol and drinking are often socially meaningful to people, and how these meanings are at the core of their culture. As a result, in this period after 1960, the anthropology of drinking took a major step away from studies of alcoholism and alcoholics to studies of drinking in the ordinary lives of both elites and those without power. In this turn, alcohol was increasingly viewed as a commodity and as a social and cultural icon.

This was a period in which the anthropology of drinking was certainly undergoing noteworthy changes, which its own participants sought to chronicle (Heath, 1987b). Anthropologists continued to focus on drinking rituals and other practices related to alcohol, but did so in ways that tied drinking to other important aspects of social life. This approach clearly demonstrated much that had begun to define symbolic anthropology in the postwar period. It also offered new windows on a growing interest in the field of anthropology overall, namely in the recognition and understanding of social and cultural identities, and the practices that helped to define sameness and otherness. This is one reason why Douglas (1987b) and her collaborators were widely appreciated for their role in integrating older and newer anthropological interests. In this very real sense, as a counterpoint to the chronology offered here, the anthropology of drinking may be approached chronologically in terms of the periods pre- and post-*Constructive Drinking*.

Current Trends, 1990–Present

The generational explosion in research, writing, and teaching in the anthropology of drinking, which greeted the last years of the old and the first of the new century has paralleled global scholarly attention to issues of identity, power, and agency. These issues are in turn integral parts in the scholarly investigation of globalization, neoliberalism, and late capitalism. However, despite the growing numbers of researchers in the anthropology of drinking in this turn of the century transition, and the much heavier attention to theory that is found in a great deal of this recent anthropology of drinking, alcohol is still a relatively minor research focus in global anthropology, and anthropologists are still a minority in the wider field of alcohol studies (Hunt and Barker, 2001; Dietler, 2006). Nevertheless, anthropologists have helped to foreground issues of culture in the comparative social science of drinking, and have gone a long way to combat ethnocentric perspectives in national and international scholarship, especially in regard to perspectives on drinking and pathology that dominate other fields (Dietler, 2006).

The anthropology of drinking today is in many ways a broad reflector of the diversity in theory and method to be found in the related domains of ethnography and anthropology. Many studies of alcohol and drinking address issues of power, inequality, and identity that are at the narrative heart of postmodern writing. But alcohol and drinking also serve as focuses in political-economic analyses of past and present imperialism, colonialism, and postcolonialism (Singer, 1986; Kasmir, 2002; Dietler, 2006). Both of these major trends often approach alcohol as material culture and commodity, and drinking as a practice of support or subversion within wider, rapidly changing, global flows of people, ideas, goods, and services. For example, alcohol as embodied material culture (Dietler, 2006: 231–232) has become an important focus in many strands of anthropology today, including archaeology, which trace commodity chains across the globe and over the years.

Anthropologists have increasingly viewed alcohol as both an agent and a symbol of globalization. In this vein, alcohol and drinking serve as actions and symbols that matter in local, regional, and national affairs, including various forms of social and cultural identification and identity. The anthropology of drinking often sees alcohol as a commodity of symbolic importance in society, but also as an element in economic and social processes of production, distribution, and consumption. It increasingly treats drinking as a public practice that is significant in many other formal and informal behaviors, in international, national, regional, and local arenas. But most significant of all, alcohol and drinking are analyzed by most anthropologists today as elements of group culture and identity.

Alcohol and drinking are meaningful to people, because they say something about people to themselves and others, in processes of social identification that frame if not help to create ethnic, national, class, gender, sexual, and other identities. While drinking is very often a loud and obvious public event involving various forms of social performance, it is also just as often a form of silent language that communicates much about who people are and who they think they are, even when an individual drinks alone in the corner of the room (Turmo, 2001). Drinking alcohol is therefore often a key practice in the expression of identity, and as such it is a building block in the construction of local, national, and global cultures. But drinking is not just an expression of identity. It is a practice through which identity is embodied, performed, and transformed (Dietler, 2006). Anthropologists in greater numbers have begun to see the relationship between drinking and identity as a fruitful field for ethnographic investigation into ways in which local, national, and global identifications emerge and change. A great deal of this work has also benefited from new and more cross-disciplinary communication, much of which is being published in volumes that specifically address issues of culture, history, and identity (de Garine and de Garine, 2001b; Wilson, 2005b; Schiefenhövel and Macbeth, 2011). In fact, the relatively minor field of alcohol studies in anthropology is itself often the subject of historical analysis, testament to its continuing strength as a subject of study within professional anthropology, but also as a means

of interdisciplinary communication and a form of applied research (Marshall, 1984; Heath, 1987a, 2000; de Garine and de Garine, 2001a; Hunt and Barker, 2001; Dietler, 2006).

Throughout this expansion in the anthropology of drinking over the last generation of scholarship, ethnographers have used the full methodological and theoretical toolkits available to them, including qualitative and quantitative methods, participant observation, network analysis, all forms of surveying, and participation in multidisciplinary projects (Heath, 1987a). The benefits of this professional flexibility has been tempered somewhat by other forces that have constrained and molded recent research and scholarship. Some of these constraints come from within anthropology itself.

In their efforts to theorize cultural change in the years after the ethnographic critiques of the 1980s, anthropologists have increasingly found it difficult to define or determine boundaries to culture and society, or to seek cause and effect relationships in culture. Instead, many ethnographers are content to chronicle their own and their respondents' experiences, and to narrate the narratives offered by respondents. This turn in ethnography, which may be considered to have been, and perhaps still is, hegemonic in certain anthropological circles, has affected the anthropology of drinking since the 1980s. In a scholarly environment where ethnographers, as observers or as participants, do not accept that they have the authority to ascertain processes of cause and effect among the groups of people they study, there has been a falloff in attempts to delineate social and cultural groups and institutions, such as, for example, communities, ethnic groups, and nations. While ethnographers are still called upon to conduct studies that may contribute to applied research, in work that is intended to have some policy appeal, they are finding it increasingly difficult to function with analytical categories that are expected to allow better cross-disciplinary collaboration. These categories, such as race, ethnicity, class, and nationality, are still valued in alcohol studies beyond anthropology, and anthropologists' reluctance to use them has resulted in vague and inconsistent social categorization that is often of little comparative significance (Heath, 1987a: 106).

This is an important consideration to anthropologists who seek public funding of their research projects, and is perhaps especially significant to those who strive to understand the relationships between health, disease, and drinking. In the USA, for example, public support of anthropological research on alcohol and drinking has been predominant for projects that see alcohol and drinking as social and medical problems that need cures. Because alcohol is linked to other drugs to which the government is opposed, the public and political war on alcohol and drugs in the USA has led to new attitudes and new policies in regard to alcohol, which in turn has had funding and policy effects, which favor certain approaches to drinking over others. One main result of this funding environment is that it has become more difficult for ethnographers to design projects where they are able to observe and analyze normal and everyday drinking practices, and the roles of alcohol and drinking in ordinary and extraordinary rituals, customs, and social and cultural institutions (Hunt and Barker, 2001: 171). The continuing emphasis on alcohol and drinking, as detrimental to health in certain research and funding quarters, also tends to mask the health benefits of drinking, for individuals and groups (Heath, 2007).

Despite these policy and funding constraints, however, anthropologists continue to study alcohol, drinking, and identity, and to do so at every level of sociocultural integration and differentiation (Wilson, 2005a,b). With a particular emphasis on drinking practices and individual and group agency, contemporary studies in the anthropology of drinking focus on the qualitative and quantitative dimensions of spatial, temporal, behavioral, and aesthetic distinctions in drinking. These distinctions, among others, mark sameness and difference in the processes of social identification (Dietler, 2006: 236).

National identity and identification are among the principal focuses of this research on drinking and identity. While this has been a global anthropological interest, it has been a particularly productive area of scholarship in Europe, in regard to nations that are long associated with alcohol and drinking, whether as a form of national branding (Wilson, 2005a), as a form of national and regional integration (McDonald, 1994a; Demossier, 1997, 2010), or as a form of national definition and resistance (Kasmir, 2002, 2005). In most of these studies, drinking is seen to be the stuff of everyday life and quotidian culture, that at the end of the day may be as important to the life of the nation as are any of its other traditions, values, and practices.

Perhaps the most important and pervasive form of identity associated with alcohol and drinking worldwide is gender (Dietler, 2006), and this has begun to have an important impact in the anthropology of drinking through the growing number of studies of culture, alcohol, and identity among young and old males and females (McDonald, 1994b; Hunt et al., 2005). As a recent review of anthropological and archaeological perspectives on alcohol has indicated (Dietler, 2006), in the last 20 years, complementing studies of national and gender identity, anthropologists who work on how culture and identity intersect with alcohol and drinking have created sizable and provocative bodies of work on politics, political economy, colonialism, and religion.

Today, anthropology continues to infuse approaches to drinking in other scholarly disciplines, particularly due to shared concerns with alcohol and culture, historically as well as in contemporary global and local affairs (Schiefenhövel and Macbeth, 2011). The anthropology of drinking has taken on more significance lately with the growing scholarly interest in all forms of popular culture and leisure activities, such as sports (Mitchell and Armstrong, 2005), but even in these intersections the importance of drinking to widespread and fundamental political, economic, and social values is apparent (Kasmir, 2005). This convergence of alcohol, culture, and politics may best be seen in ways in which anthropologists seek to affect popular impressions of what drinking practices mean and do in contemporary life, as, for example, among college students who deal regularly with the illegal and legal dimensions to binge drinking (Chrzan, 2013). But no matter how far anthropology has traveled from its own historical and methodological roots, it still must deal with the forces of tradition and change that are tied to drinking and culture (Demossier, 1997; Collinson and Macbeth, 2011). It must also deal with the forces of tradition and change in its study of drinking. It is

not surprising then that anthropologists continue to contribute to disciplinary and cross-disciplinary research in alcohol and health, despite the widely held anthropological position that most people drink alcohol without much observable harm, and anthropology as a field is not prepared to offer any immediate or easy solution to alcohol-related health problems (Johansson, 2001). It is also clear that, given the two major trends in contemporary research in the anthropology of drinking, namely those who see alcohol and drinking as problems to be solved and those who see them as cultural practices with various positive and negative roles, there is little chance of achieving a framework for a unified theoretical approach to the anthropology of drinking (Hunt and Barker, 2001).

It may be expected that the anthropology of drinking will grow in size and interest in the near future, due in large part to its recognition as a trope if not a force in processes of identity and identification in wide social scales, including the global. Alcohol is among many commodities that spark intense emotions. As such, it will continue to focus collective scholarly attention on economic, cultural, social, and political globalization. Ongoing debates on the nature and reach of globalization, and its impact on culture and identity worldwide, will ensure increased anthropological research into the production, consumption, and construction of alcohol and drinking.

Abstract

Peter F. Drucker was one of the first academics to analyze a phenomenon scarcely understood before his time, namely the mass expansion of the management profession, and to set out the tasks of this new discipline in so many words, the first to formulate them, then. In 1954 he sketches the tasks of a manager in five points: a manager sets up goals, a manager organizes, a manager motivates and communicates, a manager assesses results, and a manager develops and brings people on, not least themselves. Practitioners of management nowadays talk about *management by objectives*; they direct *profit centers*, motivate *knowledge workers*, *decentralize* structures, *do things right* (*efficiency*) and *do the right things* (*effectiveness*), or improve *customer orientation*, all concepts from Drucker's mental laboratory.

Peter F. Drucker's views about business, management, and social sciences are American in origin, though multidisciplinary by his European roots and upbringing. With a broad background, Peter F. Drucker's understanding of law, history, art, and all the liberal art disciplines made him a prominent management thinker. Drucker always maintained his European perspective on the world, one that understood that no one culture has all the answers (Handy, 2010). The Vienna-born (1909) Drucker, a professor of management at the Graduate Business School of New York University from 1950 and a professor of social sciences and management at Claremont Graduate University from 1971 to 2002, had a huge influence mostly on management practice. His wide influence manifests itself in the fact that he is not only well known in America and Europe but just as well in Asia. And his ideas continue to exercise a huge influence on the business world right up to today. Before his academic career Drucker worked as an investment advisor, journalist (business and foreign affairs), securities analyst, and management consultant. With his personal experiences on totalitarianism in 1933 escaping Hitler's Germany, he saw management mainly as a social function and an essential contribution to a free society. For Drucker, a free society needs strong institutions (Drucker, 1939). The alternative to autonomous institutions that function and perform is not freedom for Drucker, it is totalitarian tyranny (Drucker, 1973). And high-performing and self-directed institutions depend on excellent management in all sectors of society, in the for-profit, nonprofit, and public sector. Drucker's ideas have been dispersed in his 39 books from 1939's *The End of the Economic Man* to *Managing in the Next Society* published in 2002. Drucker had a profound empirical attitude while meeting with ordinary management practitioners and consulting them. He became an advisor to many significant twentieth-century leaders from all sectors of society in America, Europe, and Asia. Drucker was one of the first scientists to analyze a phenomenon scarcely understood before his time, namely the mass expansion of the management profession, and to set out the tasks of this new discipline in so many words, the first to formulate them, then. Drucker developed management into an application-oriented discipline, the basis for which he outlined in the work *Practice of Management* where he points out that, rarely in history has a new institution proved itself so indispensable in so short a time. And for Drucker it still is rarer that a new institution capable of establishing itself "with so little opposition, unrest and controversy" (Drucker, 1954: p. 4).

In his book *The New Realities*, he offered a definition of management as a liberal art: "Management is thus what tradition used to call a liberal art – 'liberal' because it deals with the fundamentals of knowledge, self-knowledge, wisdom, and leadership; 'art' because it is practice and application. Managers draw on all the knowledges and insights of the humanities and the social sciences – on psychology and philosophy, on economics and history, on the physical sciences and ethics. But they have to focus this knowledge on effectiveness and results – on healing a sick patient, teaching a student, building a bridge, designing and selling a 'user-friendly' software program" (Drucker, 1989: p. 231).

Management as Discipline

In his early work Drucker's most important contribution was to develop management as an independent subject area to be treated as sovereign unto itself. He described what were still at that time the initial innovations in business studies as insufficient for the tasks of leadership. He coined many terms and concepts for the new mass profession of manager. Many of them have today gone over into everyday language use. Among others, the terms, 'profit center,' 'decentralization,' 'knowledge worker,' and 'management by objectives' originate with him.

In spite of his down-to-earth-approach, Peter Drucker never himself worked as a manager or as an employee of a large firm. He styled himself a 'bystander,' one who looks on. He observed organizations and managers from a distance and independently. He remained an independent thinker and was more of an intellectual than an academic. (Drucker declined even chairs from Harvard and Stanford for having more freedom and less academic obligations.) For Drucker management was less a form of scholarship than it was, first and foremost, practice. In the discipline of management what matters is working out *what needs to be done*. Drucker became a philosopher of management who went on to pursue practical philosophy (Weber, 2009).

As an experienced journalist, by the 1940s Drucker knew full well that he had to develop completely new concepts and

lines of inquiry for his project of formulating the discipline of management. And in addition, he was quite aware that, if he wanted to convince the practitioners of management, he had to write precisely and intelligibly. The great challenge for authors and consultants in management consists in formulating the discipline's contradictions and paradoxes so that practitioners, when they look for advice, are perhaps a little confused but never overly. And that goes for managers too. When they make decisions, their organization observes these decisions. Decisions do not actually exist in the heads of those doing the deciding. They are only effective, if they are perceived as communicative events, which have to come so nice and tightly packaged that the contradictions and the complexity underlying the decisions cannot be recognized, or scarcely so, and subsequent decisions can follow on from them (cf Luhmann, 2002). The art of management is to employ language adroitly. The art consists in seeing complexity, making what is undecidable decidable and blunting the edge of possible critics of current decisions, who may be sensing pure arbitrariness, with ready, clear, precise, and, as far as possible, rational justifications. Drucker saw himself in the tradition of Chester Barnard (1886–1961), who was one of the first to tackle practical philosophy and organizational theory and posed large-scale questions going beyond the initiatives from Frederick Taylor and Henry Fayol in business studies (Drucker, 1954: p. viii). Barnard defended himself by differentiating between two ways of talking about management: abstract-theoretical and generally comprehensible-practical. He maintained that he needed both styles for his activities and could only understand what he was doing in practice through his theory. For Barnard, managing meant acting intuitively, without being able to say what knowledge was guiding you (Barnard, 1938).

In Drucker's first mag*num opus*, *The Practice of Management*, he gives one section the title of *A Philosophy of Management* (Drucker, 1954). Drucker's method became the Socratic dialogue and large-scale questions. He put the practical philosopher's question to managers: *What would you do, if* …? With managers, he discussed the question of how they should act and how they should reflect on their everyday activity.

In Drucker's approach management is an institution and a source of innovation in society, where managers can take risks in the sense of an organization's goals. That is because there is no longer any center in society, where all the weak signals from the surroundings could be collated and decisions made under clear-cut conditions. Organizations and management, however, observe quite specific differences and decide with regard to their actually defined performance. They develop a particular, potentially innovative product and duly throw another one out of the program. They offer a new therapeutic procedure and forego another one. They rehearse a new piece for the theater and discontinue another one.

In premodern societies, despots could still determine, for example, religious allegiance or the value of currency, or they could cut swathes across a full-grown city and force urban boulevards through. In a society where everyone knew their place, the great simplifiers could still create circumstances that were clear-cut. Today, there is no reality that all citizens share. In management, it is not a question of optimization any more but of finding a balance. Organizations have become complex systems, which have to try to advance themselves in a complex environment, and they do, for their part, contribute to society becoming ever more differentiated. This is where Peter Drucker's pioneer work comes in. He was originally an intellectual and a social scientist, and it was almost by accident that he came to engage intensively with organizations and the running of them. Drucker began to observe the practice of management and to set it out from a historical perspective. He accompanied managers in their everyday routines, as, for example, Alfred Sloan and the management of General Motors, whose behavior when making decisions he studied for 2 years in the early 1940s. Drucker worked out the essential elements of this new mass profession and looked beyond the surface presented by 'charismatic' leaders in firms. He was concerned with formulating the essence of the discipline, with contributing to it and making it something you could learn – and perhaps teach. His questions went deeper than those of his contemporaries. What accounted for the success of this particular person, who had the reputation of being charismatic? What tasks have they accomplished? What tools can they wield? What are their basic working principles? Drucker was one of the first thinkers to analyze the proliferation of business leaders en masse – until then a social phenomenon scarcely understood – and to set down the tasks of this new discipline in words, the first to formulate it. In 1954, he wrote about the new mass phenomenon of management: "Rarely, if ever, has a new basic institution, a new leading group, emerged as fast as has management since the turn of this century. Rarely in human history has a new institution proven indispensable so quickly; and even less often has a new institution arrived with so little opposition, so little disturbance, so little controversy" (Drucker, 1954: p. 3).

Knowledge Worker's Productivity

Peter Drucker's suggestions for management as a liberal art aim to connect up two not easily integrated elements of organizing: *optimizing* organizations as places, where people make decisions as rationally as possible and promote the development of organizations in terms of efficiency and effectiveness, and *motivating* their members, something that succeeds particularly well when they are granted an independent existence with enough room for self-organizing. If the way management works emphasizes calculations and techniques, then the second element, the social system, is often ignored, and people become mere employees working to rule. Drucker's simple question, "how do we increase a knowledge worker's productivity?" harbors some of the tricky questions that modern management has to tackle. Raising productivity among knowledge workers does indeed depend on individuals, but they can only apply knowledge cooperatively and in organizations (Drucker, 1994). There are chances proliferating out of that for every practitioner, whether manager or knowledge worker, but also totally new questions and problems. Each and every member of a knowledge-based organization will have to learn how to explain to others – who lack the same basis of knowledge – what makes this specialized knowledge so significant. Everyone will be personally responsible for their

knowledge, making a contribution to organizations, and even, in fact, to society at large.

That causes the basic principles of management to shift. In Drucker's *next society* (Drucker, 2002) the challenge will be that individuals, groups, and knowledge workers can explain to others what they are about. We will observe management to see if it employs language people can understand. And beyond that, knowledge workers, clients, and interest groups are continually wanting proof that managers are listening to them. Alongside what has become a matter of course – the job of running organizations effectively – more and more depends on whether you cultivate a communicative style of leadership. Working in an organization of knowledge workers means being able to communicate (cf Baecker, 2003).

The Practice of Management

In 1954 Drucker wrote the first 'true management book' (Drucker, 1954: p. viii) and looked at management as a whole, as a distinct function, and as a specific work. He sketches the tasks of a manager in five points: a manager sets up goals, a manager organizes, a manager motivates and communicates, a manager assesses results, and a manager develops and brings people on, not least themselves.

Management by Objectives

Drucker's fundamental principle for management is concentration! Management has to clarify goals. He invented the concept *management by objectives*, which may be Drucker's most well-known management paradigm. And that does not, in fact, mean the classical variant of a falsely understood *management by objectives*, dealing in causes and effects, but management in a form capable of creating 'a universe of pattern, purpose, and process' (Drucker, 1959). If, as a manager, you are not constantly asking about the results your organization wants to achieve, then nobody knows what has primacy.

Drucker's suggestion on this is predictably simple: management repeatedly prepares organizations for new challenges by asking repetitively large-scale questions. The focus is secondly on the commercial index-number, the incremental improvement, or the next reorganization-project. Firstly management has to regularly pose the apparently simple question, *what is our mission, how can we create a customer etc.*? In this sense, management is not leadership qua direction by individuals, but the shaping and steering of entire organizations in their environment. Management does not mean leadership for your direct subordinates but for all members of an organization. And when the organization has reached a certain size, management can only lead by indirect influence and scarcely has sufficient information anyway. Management achieves joint performance by making the survival of an organization the overriding goal. Profit in an organization as a social system is only a means to this end.

Drucker's famous anecdote illustrates the importance he places on self-management when three stonecutters were asked what they were doing. The first replied: "I am making a living." The second kept on hammering while he said: "I am doing the best job of stonecutting in the entire county." The third one looked up with a visionary gleam in his eyes and said: "I am building a cathedral" (Drucker, 1954: p. 122). The management challenge consists in leading ordinary people to perform extraordinarily.

Management Means Communicating

Managers do all they can to ensure that employees, who have all become problem-solvers in modern organizations, get a hearing for their suggested solutions in a culture of open discussion. Managers have, therefore, to reduce the intervals in hierarchies. They have to tear down the walls between *white-collar* and *blue-collar* workers. Organizations should be only interested in 'creating a customer.' Every communication in them must aim at this goal. That means every function in firms changes; every member of the organization supports those who are currently achieving the results in firms. And this will only succeed if it gets communicated and understood. In an organization that communicates, no one person is privileged any longer as the only one people report to. For Drucker the system must serve the worker in a knowledge worker workforce (Drucker, 2002). If someone says about problems, "it's nothing more than a communications problem," then people need to prick up their ears. Communication has become the hardest of all problems.

Systematic Abandonment and Change

Old habits, long-tolerated weakness, accumulated mementos, or deeply ingrained routines can threaten organizations' survival. The messy-syndrome, the love of disorder, only appears relatively rarely among people, but for organizations it is almost a typical phenomenon. Continuously abandoning things is a permanent task which has to be organized, so someone has to take responsibility for it. For Drucker, abandonment becomes a starting point for processes of change and innovative solutions (Drucker, 2008).

Drucker's famous question to Jack Welch, a former CEO of General Electric "if you weren't already in the business, would you enter it today?" had radically changed his company. Every organization which asks itself this question every 3 months and bases all its decisions on it – that is the advice of Drucker – will change beyond recognition. Every organization only survives long term if its results head the field, if everything is taken care of perfectly. Mediocre work has to be abandoned, as otherwise self-confidence within an organization starts eroding.

Yet Drucker also recommends that managers have to ask details about which processes are too fat, about where, going completely on value-stream, *leaner* organization is possible. What do you have to leave out, which processes contain superfluous elements, where is too much being produced, where are there waiting times, unnecessary trips, high levels of stock, and repeated mistakes?

The next management has less and less time to recognize what needs removing. What means success today, will perhaps have to be thrown out tomorrow.

Strengths and Weaknesses

In a society of organizations based on knowledge, everybody starts out at zero. Everyone starts out with the same 'total

ignorance.' When senior executives promote their people, challenge them, and encourage them, they put three Drucker questions: What are your strengths and what should you put work into? What should this company expect from you and in what time span? And what information do you need to do your work and what information do you owe? Managing knowledge workers means devoting time to them; understanding their work and what makes them tick; and building up a personal relationship with them, to mentor them and to listen to them, to challenge them and to encourage them. For managers, it is always a question of reaching employees and contributing toward them being able to grow (Drucker, 2002).

Entrepreneurship and Innovation

The corporation as we know it, will not survive in this century, Drucker predicts. "Legally and financially, yes, but not structurally and economically" (Drucker, 2002: p. 68). In stable times, when developments can be expected to a certain extent, it is sufficient to make things better. In times of 'discontinuity,' however, it is a question of 'doing things differently' (Drucker, 1969). All organizations have to live with the concomitant risks. Defending the past – not innovating – is much more risky than shaping the future.

Rerum novarum cupidus, greedy for something new, is how a Roman poet described human nature. But how do new things come into the world? For Drucker, it is not through the 'typical entrepreneurial personality.' He maintained he had not come across any such personality. Entrepreneurial activity creates new things through systematic procedures. Firstly, when entrepreneurs conduct meetings, there is always a clear division between two perennial items for discussion: the problems needing solutions and the opportunities not to be missed. Secondly, people in entrepreneurially managed organizations take notice of the staff who perform better and ask them, "how do you do that?" Thirdly, entrepreneurs get together at certain times with the next generation from all sectors and ask them about their ambitions, opportunities, liabilities, and their views about the firm. Where should entrepreneurs enter new territory, where develop something new, where dispense with what is obsolete? The innovation process also has to take place with people involved from outside the firm, with partners, clients, and the social environment.

Managing and Networks

Peter Drucker always understood the world of management as a social system and as a profession he could influence by communication and networking. The profession of management is based on communication. Managers are communicating for most of their time (Mintzberg, 2009) and building human relations, and that naturally means networks. If they fulfill this central task well, then a climate of trust grows and organizations are able to handle more complex tasks.

For Drucker management innovations will arise particularly through combining management ideas from different sectors of society. Being receptive brings about complexity and variance in management. Drucker's experiences with nonprofit organizations have had become a central source for his ideas. The social function management has is not something we can reduce to processes of optimization. Accordingly, management would also comprehend social ecology: management as a 'bridge between civilization and culture' (Ueda and Isaka, 2010). For Drucker, social ecology means observing phenomena from societies and communities and from business administration at one and the same time. What motivates a knowledge worker does not depend only on job satisfaction. Committing to public service and taking on social responsibilities would be a decisive factor in managers attaining personal maturity. What every organization can learn from the volunteer organizations is their ability to attract and to retain members. In Drucker's management approach organizations have to accept the fact that you have to treat your staff as 'volunteers.' Workers carry their ideas in their heads and could go to any other organization the next day. Because Peter Drucker himself was so excellently connected in management, he saw phenomena only hubs can see. In clusters, from a bird's eye perspective, as an observer of management, he foresaw many developments in organizations and in society. Drucker was a second-level observer. He would observe managers. He would observe advisers as they observed managers. He would observe the colleagues of management thinkers, as they observed managers and advisers. He was well aware of his position as a management network hub. Drucker researched into and advised all three sectors of organizations: profit-oriented, nonprofit, and public organizations. He knew many influential managers of large organizations personally, in all the important industrial nations. And he was in daily contact with the next generation of leaders, who came to him in streams from all over the world, with the students of the Claremont Graduate School and the young managers, advisers, and scholars, who visited him at home until he passed away in 2005.

Management Ethics

For managers, it is always a matter of being a role model too. What counts is resisting the enticements of status and resisting privilege, being aware of the responsibility toward people, and understanding themselves as part of a social system. Drucker despised that parasitical trait some top managers display and advocated spurning the 'golden parachutes' of payoffs in millions. Management is a young profession, which has so far been brought in without much resistance in society. If modern society wants to continue the success of this function, then Drucker claims to develop a minimal code of ethics in the management profession, one which can, for instance, borrow from the Hippocratic oath: *Primum non nocere*, above all things, do no harm to anyone.

Managing Complexity

Peter Drucker's writings, lectures, and epigrams offer a way to tolerate the paradoxes of management's everyday life and the lack of oversight. He helped both to reduce complexity and to increase it (Weber and Kulothungan, 2010). Drucker took trouble to test his every ideas and concepts to see if they worked. His disciples confirmed that he tried to use only words and terms every manager could understand without needing a dictionary. His oeuvre intended to be linked directly to the

practice of management. Economic scientists ignored him a long time and still do because of his inductive and application-orientated approach. Management designed as an application-orientated discipline helped to widen the view of practitioners and helped them to trust themselves. He encouraged them to define management as a communication system where observers observe how they are observed. Drucker assisted managers to vary their actions and to adjust their expectations in permanent self-assessment, constant resharpening, constant refocusing, and in never being really satisfied (Drucker, 2008). He backed managers to deal with complexity in a *non*strategic manner. He encouraged them not to analyze everything and spend much time on long-term planning. Drucker taught managers to look behind simple cause-and-effect chains and showed the blind alleys organizers are running in (Weber, 2007). Instead of trends and belief in progress, Drucker was interested in the practice of innovation. Even if he correctly foresaw several future developments, Drucker denied to predict and had the idea of a future that does not just happen, but instead is designed today to make for a different tomorrow. Drucker's advice that strategy and operational planning have nothing to do with future decisions. It is formulated *right now* and so it is also only *right now* that it can be correct or false: false or correct as regards a future envisaged in the now. Future is always unpredictable but today's decisions will impact the future (cf Malik, 2010; Baecker, 2010). Managers in the age of complexity are innovators in finding and bridging gaps where others see only labyrinths. 'Managing in the next society' means to be fascinated and challenged by complexity. In an era of uncertainty managing means to act always as 'to increase the number of choices' (Foerster and Poerksen, 2003).

Conclusion

We have Drucker to thank for the admonition about not confusing the art of management with a science. Management repeatedly prepares organizations for new challenges by asking large-scale questions. It encourages workers doing a job either perfectly or not at all, because that is the only way core-values in the organization can come about and can help an organization as a social system to survive. Profit is only a means to this end. Drucker's oeuvre consists a paradoxical intervention: heralding the new and advocating communication and repetition (Baecker, 2010). Who could argue against innovating? Who could dispute that repetition and unlimited patience is necessary for management communication if the organization wants to innovate? And who can deny, that you need managers with tolerance for ambiguity in an organization that has been founded for exercising routines?

In the age of complexity, Peter Drucker's *next management* has to try to strike the right balance between investment and innovation. Every objective, every plan-of-action an organization develops must be formulated *right now*, and so they can also only be right or wrong *right now*. Every philosophy of management, which puts too much stress on innovation for its own sake, may indeed make the pendulum of management trends swing the other way, but it does run the risk of advocating *newness for newness' sake* and risks recommending actions that underestimate pressures from the immediate present. That causes the basic principles of management to shift. The next management will be talk, decision, and action (cf Brunsson, 1989). Drucker characterized this shift to talk that management employs language people can understand. And beyond that, knowledge workers, clients, and interest groups are continually wanting proof that managers are listening to them. The other shift is that management decides in a way to increase the number of choices. And last but not least this shift is a bias for action and a permanent redesigning of planning (Drucker, 1973). The job of running organizations effectively more and more depends on whether a communicative style of leadership is cultivated. Managing and working in the *next society* is for Drucker being able to communicate. Peter Drucker's management philosophy helps managers to widen their view and to trust themselves. He helps them to define management as a liberal art and a communication system where observers observe how they are observed. Drucker encourages managers to vary their actions and to adjust their expectations in permanent self-assessment, the "first action requirement of leadership: the constant resharpening, constant refocusing, never being really satisfied" (Drucker, 2008: p. 5). Drucker helps us to deal with complexity in a *non*strategic manner. Managers do not have to analyze everything and spend much time on long-term planning. They can only solve the problems of today. Drucker teaches us to look behind simple cause-and-effect chains and shows us the blind alleys we are running in (Weber, 2007).

With this kind of management approach professional managers are able to develop a rich and complex communication stage where observations are ambivalent. Managers in the 'next society' are innovators in finding and bridging gaps where others see only labyrinths. Managers in the 'next society' are fascinated and challenged by complexity, they 'act always as to increase the number of choices' (Foerster and Poerksen, 2003).

Drug Control: International Aspects

Abstract

Systems to control problems from psychoactive substance have included prohibitions, prescription systems, state control, and licensing, but did not extend internationally until the twentieth century. International treaties now include three drug treaties, and conventions on tobacco and against doping in sport, but not for alcohol. The pattern and content of the treaties reflect the wide conceptual chasm in the mid-tenth century between prohibited drugs and alcohol and tobacco. The international drug control system has diminished use of some prescribed drugs, but has been ineffective in suppressing illicit markets. Prototypical patterns of psychoactive substance use are medicinal use, customary regular use, and intermittent use – the last often invested with drama. In the last two centuries, a fourth pattern of use has become conceptualized as addiction. The social handing of psychoactive substances has been a fertile ground for social science research, with an emphasis on the social construction of problems and critical analyses of addiction and other conceptualizations, along with positivist work measuring and analyzing social and health problems associated with substance use. Social science work on international aspects has been limited.

'Drugs' include a wide range of psychoactive substances, including tobacco, alcoholic beverages, coffee, and pharmaceuticals, as well as marijuana, opiates, and cocaine. Prototypical patterns of use include medicinally, regularly as a 'banalized' part of daily life, and intermittently. In the modern world, addicted or dependent use is recognized as a fourth pattern.

Systems to reduce problems from drug use have included prohibitions, prescription systems, state control, or licensing systems, as well as no special controls. In the wake of efforts to prohibit alcohol, an international narcotics control system was set up starting in 1912, ensuring medical supplies but prohibiting other use. Since 1970, the system has expanded beyond opiates, cocaine, and marijuana to cover synthesized medications and precursor chemicals. Other international control systems have emerged more recently: an International Convention against Doping in Sport (2005) to control performance-enhancing drugs (including some psychoactive substances) in sports, and a Framework Convention on Tobacco Control (2003).

Social science work has mostly been funded because of social concerns about alcohol and other drugs, but researchers have often strayed beyond the official frames for their work. Thus there have been traditions of constructivist analysis of governing images of alcohol and drug problems, and critical analysis of addiction concepts. Analysis of the developing international systems for control of psychoactive substances has so far been primarily in terms of historical and policy studies (e.g., Braithwaite and Drahos, 2000), although the effects of the systems' provisions show up in studies in all social sciences.

Although the term 'drug' has a wider range of meanings, we are concerned here with substances that are psychoactive, that is, which alter the mental state of humans when ingested. Such drugs have been both prized and feared throughout human history. They have long been a substantial item in international trade, and indeed concerning the European colonial systems of 1500–1960 they have been described as the glue of empires (Courtwright, 2002). In the twentieth century, they also become the subject of ambitious international control structures. In connection with such control structures, brief consideration is given, too, to performance-enhancing drugs, a category overlapping with psychoactive drugs.

Psychoactive Drugs and How They Are Used

There are a wide variety of psychoactive substances, naturally occurring and synthesized, including tobacco, alcoholic beverages, coffee, tea, chocolate, and some spices, as well as substances legally available primarily through medical channels such as benzodiazepines, cannabinols (including marijuana), opiates (including heroin), and cocaine. Such substances often have other use values, along with their psychoactive properties (Mäkelä, 1983). Users may like the taste, or the image of themselves that the use conveys. Use may be a medium of sociability, or part of a religious ritual. Some substances have other useful properties; alcohol, for example, is a source of calories, and is the solvent in many tinctures and medicines.

Psychoactive drugs differ in their metabolic pathways and mechanisms of action in the human body, in the strength of their effects, and in the states of mind and feelings they induce. In particular, it is easy to become intoxicated with some substances – alcohol is a prominent example – while it is much less likely with others. But the effects of drug use are also powerfully dependent on the pattern of use, and on set and setting – that is, the expectations of the user and of others present, and the context of use (Zinberg, 1984). While the psychoactive effect of tobacco may not even register in the consciousness of a habituated cigarette smoker, in other circumstances the effect of tobacco use may be so strong that the user is rendered unconscious, as early Spanish observers reported concerning native South Americans.

Three social patternings of psychoactive drug use can be distinguished as prototypical: medicinal use, customary regular

use, and intermittent use. In many traditional societies, particular drugs or formulations have been confined to medicinal use – that is, to use under the supervision of a healer to alleviate mental or physical illness or distress. For several centuries after the technique for distilling alcoholic spirits had diffused from the Arab world to Europe, for instance, spirits-based drinks were regarded primarily as medicines. This way of framing drug use has been routinized in the modern state through a prescription system, with physicians writing the prescriptions and pharmacists filling them (Babor et al., 2010). Drugs included in the prescription system are usually forbidden for nonmedicinal use.

Where a drug becomes a regular accompaniment of everyday life, its psychoactivity is often muted and even unnoticed, as is often the case for a habitual cigarette smoker. Likewise, in southern European wine cultures, wine is often differentiated from intoxicating 'alcohol'; wine drinkers may be expected to maintain the same comportment after drinking as before. We may call this a pattern of 'banalized use': a potentially powerful psychoactive agent is domesticated into a mundane article of daily life, available relatively freely on the consumer market.

Intermittent use – for instance, on sacred occasions, at festivals, or only on weekends – minimizes the buildup of tolerance to the drug. It is in the context of such patterns that the greatest attention is likely to be paid to the drug's psychoactive properties. The drug may be understood by both the user and others as having temporarily taken over control of the user's behavior, and thus to explain otherwise unexpected behavior (Room and Collins, 1983). Given the power attributed to the substance, access to it may be limited: in traditional societies by sumptuary rules keyed to social differentiations, in industrial societies by other forms of market restriction.

A fourth pattern of use is commonly recognized for certain drugs: addicted or dependent use, marked by regular use, often of large doses. Since the pattern of use of the drug in question is not defined in the society as banalized, addiction is defined as an individual failing rather than as a social pattern. While attention is paid to physical factors sustaining regular use, such as use to relieve withdrawal symptoms, most formulations of addiction focus on psychological aspects, including an apparent commitment to drug use to the exclusion of other activities and despite default of major social roles. An addiction concept thus also focuses on loss of normal self-control, but the emphasis is not so much on the immediate effects of the drug as on a repeated or continuing pattern of an apparent inability to control or refrain from use, despite adverse consequences. Addiction as an explanation of otherwise inexplicable behavior now has wide currency, but first became established in industrializing societies less than two centuries ago (Room, 2003).

Among the attractions of psychoactive substances is that, at least up to a certain point, they potentially enhance one or another kind of performance by the user. For instance, coffee or a cigarette may modestly improve mental performance, a limited amount of alcohol may improve dancing or other expressive activity, amphetamines may improve wakefulness on a long watch. There are also nonpsychoactive substances (steroids, beta-blockers, etc.) which can potentially improve one or another kind of performance. In particular, in the context of competitive sports, international attention has been focused on a wide variety of substances that can improve some aspect of athletic performance (Carstairs, 2003).

Problems from Drug Use, and Systems of Control

From ancient times, it has been recognized that problems can result from drug use. Formerly, the main concerns were with social and political problems seen as associated with drug use. In medieval England, the government's main concern in controlling alcohol sales was with enforcing discipline in the labor force. Violence, disturbances of the peace, and harm to dependent family members would also be commonly recognized, particularly in relation to alcohol consumption. Often it was rebellious or countercultural elements of a society which introduced or became associated with new drugs. Reacting to this, political establishments in Europe tried at first to control coffeehouses, and in Turkey and elsewhere imposed severe punishments on tobacco use (Austin, 1978).

New social concerns about problems from drug use entered the scene in the modern era. Concerns about the physical health of the drinker were a factor in responses to the English 'gin epidemic' of the eighteenth century. In the early nineteenth century, the idea of addiction became established, at first for alcohol and in the USA (Levine, 1978), and was applied also to other psychoactive drugs by the late nineteenth century. As safety became identified as a social problem in the latter era, attention was also directed to the potential effects of drinking in degrading performance of mechanical tasks. In recent decades, as the automobile became a central part of daily life, this concern became much stronger, and was extended too to other drugs.

Social concerns about problems from drug use have resulted in a variety of kinds of efforts to control availability (MacCoun et al., 1996; Room, 2000). One option has been a flat prohibition on use, or at least on recreational use. Combined with this, sometimes, has been a system for use of the substance as a medication. The prescription system in modern states is essentially a state-sanctioned form of rationing of availability, with doctors and pharmacists delegated to serve as the gatekeepers on access. A third option has been a system of state control or licensing of sales, such as the systems of alcohol control through state monopolies and licenses in North American states and provinces. Such a structure can be combined with other discouragements for use, such as excise taxes and restricted opening hours. A fourth option, applicable for instance nearly everywhere for tea and coffee, is that the psychoactive substance is treated as an ordinary commodity, with no special controls. For intoxicating substances, choice of the third or fourth option is often accompanied by 'harm reduction' measures (in the terminology of the illicit drug field), since the options involve official acceptance of the fact of recreational drug use.

Where a psychoactive substance is seen as causing great problems, prohibition of use has been a fairly common societal response. Such a prohibition on alcohol had long been imposed on all faithful Muslims by the Koran. Legal prohibition of alcohol, initially on a local basis or for special population categories such as indigenous peoples, became a feature

of some Christian societies in the late nineteenth and early twentieth centuries. Prohibition of alcohol sales extended to the national level around the time of World War I in 13 self-governing nations, including the USA, Canada (briefly), Norway, Finland, and Russia (Schrad, 2010). The USA, in particular, had some success in gaining international cooperation with its prohibition through bilateral treaties (Tyrrell, 1994). A flourishing worldwide temperance movement succeeded in pushing the European powers with colonies in Africa into adopting treaties prohibiting aspects of the distilled spirits trade in Africa (Bruun et al., 1975). These fell into disuse by the 1950s.

The alternative to prohibition in the early twentieth century was 'state control,' and comprehensive systems of alcohol control were eventually adopted, not only in the societies that had tried prohibition, but also in many other nations. These systems have been gradually weakened, particularly since 1950 (Mäkelä et al., 1981). On the other hand, in a broad range of societies there has been a steady strengthening of controls over drinking in specific circumstances, in particular over drinking and driving (Gusfield, 1981; Mann et al., 2001).

In the early twentieth century, the idea of a prohibitory regime was extended from alcohol to other psychoactive substances. In the realm of 'narcotics,' which came to refer to opiates, cocaine, and marijuana, the first international treaty was adopted in 1912, and extended globally as part of the treaties concluding World War I (McAllister, 1992). The agreement on narcotics can be seen as part of an emergent tradition of such regimes for social problems defined as international in scope (Nadelmann, 1990). A series of subsequent international agreements were codified in the 1961 Single Convention on Narcotic Drugs (amended 1972). While the system had always included provision for a legal market in narcotic medications under a prescription system, in a 1971 convention its scope was broadened to extend international control to other synthesized medications such as amphetamines, barbiturates, and benzodiazepines. A 1988 convention extended control also to 'precursor chemicals' used in manufacturing controlled drugs. By 1996, more than 240 substances were, in principle, under the system's control (Room and Paglia, 1999).

In the early 2010s, the international narcotics control system included the United Nations Drug Control Program, with about 500 staff, headquartered in Vienna. The political organ of the system is the Commission on Narcotic Drugs, with an elected membership of 53 nations. The International Narcotics Control Board serves as the control board for the legal (pharmaceutical) markets in controlled drugs. Alongside this international effort is a substantial global antidrug effort by the USA, including 751 staff posted in 59 other countries in 2007, and an annual International Narcotics Control Strategy Report to the US Congress on the extent of cooperation by each other country with antidrug actions (Babor et al., 2010: 215).

Although effective action has been taken to diminish use of prescribed drugs like barbiturates, the international system has been relatively ineffective in suppressing illicit international traffic in drugs, (Room and Reuter, 2012), and has done little to limit the very large markets in prescribed psychoactive substances, particularly in high-income countries (the U.S. consumed 70% of the world's legal supplies of opiate medications in 2003–05) (Babor et al., 2010: 86–87).

At the end of the 1990s, two other international systems for the control of psychoactive drugs were in formation. In 1989 the Council of Europe had put forward an Anti-Doping Convention, which by 2000, had been signed by 40 European countries and other countries such as Australia and Canada. This was largely superseded by a treaty, the International Convention against Doping in Sport, adopted in 2005 under the auspices of UNESCO and in force since 2007.

In October 2000, the World Health Organization began negotiations on a global Framework Convention on Tobacco Control, adopted in 2003 and in force since 2005. Many of the provisions of the tobacco treaty are 'soft law' encouraging rather than requiring specific national actions such as high cigarette taxes or prices. Unlike the international narcotics control system and the nascent antidoping system, the international tobacco control system does not attempt to prescribe prohibition of use.

In the meantime, in 2014 there is no prospect of any international agreement on alcohol control. For tobacco and alcohol, as well as other psychoactive substances not under international control, international treaties have operated in the opposite direction. The World Trade Organization and related treaties, and regional free trade agreements, have been used to weaken national and local alcohol controls (Holder et al., 1998; O'Brien, 2013). Despite shifts in biomedical and public health thinking back to viewing psychoactive substances in a common frame, in the early twenty-first century the international regimes still reflect and maintain the wide chasm set in the mid-twentieth century between the definition and handling of substances covered by the drug treaties and other psychoactive substances (Courtwright, 2005; Braithwaite and Drahos, 2000).

Traditions of Social Science Analysis

Dominant patterns of use of a drug in a society, and shifting conceptions about its use, greatly affect the size and shape of the social science literature concerning that drug. In particular, the very different sociocultural positions of 'illicit drugs,' benzodiazepines, alcohol, tobacco, and coffee in most developed societies means that the literature about these different psychoactive substances are often quite separate.

Novel substances have proved a potent catalyst in many societies in crystallizing free-floating fears about the younger generation and the future. Culturally accepted psychoactive substances, on the other hand, become deeply entrenched in the culture, although often with the potential to again become contested. Social concerns about drugs have thus often ensured substantial funding for social scientists to work in the area. For instance, a substantial part of Polish sociology was financed to work on alcohol problems in the difficult days of martial law there in the 1980s. But while much social science work has been funded and expected to proceed within the parameters of official frames, the work of sociologists and other social scientists has also played a key role in broadening the base of scholarship and understanding. For the drugs under international control, in particular, there is a discernible split in emphasis, particularly in the US, between government-funded social research and a growing tradition of critical analyses.

In the first place, alcohol and drug issues have proved fertile grounds for constructivist analyses by sociologists. Historical and comparative work has identified a number of alternative governing images or models of alcohol and drug problems, and shown that these governing images change over time (Bruun, 1971; Gusfield, 1967). Constructivist perspectives have often been combined with a positivist concern about measuring and comparing social and health problems associated with drug use, and about distinguishing problems attributable to the drug use from problems that are secondary to societal reactions (e.g., Fischer et al., 1997). Some analyses point to a function for illicit drugs of providing 'suitable enemies' for the modern state, in comparison with the 'unsuitable enemies' of tobacco, alcohol, and pharmaceuticals (Christie and Bruun, 2003).

In the second place, there is a long sociological tradition of critical analysis of the concepts of alcoholism or addiction as a disease (Room, 1983), concepts that were the dominant discourse in the last half of the twentieth century. The alcohol and drug arenas have thus figured prominently in sociological analyses of the 'medicalization of deviance' – and its demedicalization (Conrad and Schneider, 1992). Applying perspectives from Foucault and Rothman, Levine (1978) showed that the addiction concept has a history, first coming to the fore in the early nineteenth-century USA, as an explanation of the mystery of continued drinking by the drunkard, even after pledging to abstinence. Analyses in this tradition point to the centrality to addiction concepts of the focus on self-control (Valverde, 1998). The economist's concept of 'rational addiction' has also contributed to the ferment in thinking about addiction concepts (Elster and Skog, 1999).

There are as yet few social science analyses of the burgeoning international systems for control of psychoactive substances. Bruun et al. (1975) studied the development of the international drug control system until the early 1970s, but further arm's-length analysis of the expansion of this system's scope only started to appear after the millennium (e.g., Carstairs, 2005; Bewley-Taylor 2005), and arm's-length analyses of the development of new international instruments and agencies around doping in sports are as yet rare (Houlihan, 2004) and rarer still for tobacco. Work looking across the different systems (and absence of systems) of international control of psychoactive substance remains uncommon (but see Braithwaite and Drahos, 2000). Why the systems are developing separately, the nature and practicability of their goals, and their place in the developing international system, are still important topics for future work.

Drugs, Decriminalization of: Cultural Concerns

Stephen J Morse, University of Pennsylvania Law School, Philadelphia, PA, USA

© 2015 Elsevier Ltd. All rights reserved.

Abstract

This article defines drugs and decriminalization, addresses how the debate about decriminalization has changed in the last decade, considers whether criminalizing recreational drug use is a legitimate infringement of individual liberties, and provides an analysis of the costs and benefits of decriminalization, including the uncertainties involved. It concludes that the outcome of decriminalization is inevitably uncertain and that much depends on the details of the decriminalization scheme.

Introduction

The issue of drug decriminalization or legalization is whether and to what extent the state should use criminal sanctions to regulate drug-related activities such as production, sale, purchase, possession, and use. Analysis of the issue must therefore focus on consideration of the legitimate uses of the criminal law, with special attention to the moral and political rights of citizens to use drugs and to the costs and benefits of criminal prohibition. After considering the definitions of drugs and decriminalization, this article will consider how the decriminalization debate has changed in the last decade. Then, following discussion of the basic limits on the use of the criminal law, this article will address the contributions of rights and cost–benefit analyses to the decriminalization debate.

Defining Drugs and Decriminalization

Despite common belief to the contrary, there is no uncontroversial definition of 'drug' or 'decriminalization,' but clarity about both is necessary to understand the debate and to guide public policy.

Drugs

Virtually, all definitions are vague or overinclusive, permitting categorization as a drug of almost any substance that may be consumed. Some definitions are circularly dependent on legal regulations: if a law regulating 'drugs' includes a particular substance within its ambit, it is a drug if it is not so included, it is not. Vague, overinclusive, and circular definitions cannot sensibly guide public policy, especially when the state's awesome power to blame and punish for illegitimate use is dependent on the definition.

Definitional problems concerning drugs and legitimacy cannot be entirely avoided by using allegedly scientific or value-neutral medical/therapeutic or nutritional concepts. Concepts like disease and therapy are themselves valueladen and inevitably problematic and controversial. Many substances that have unquestionably legitimate medical or nutritional uses can also be used for nonmedical or nonnutritional purposes that may be of questionable legitimacy. Finally, definitions that define a substance as a drug in terms of its intended use rather than in terms of its inherent properties obscure important questions of legitimate use.

Despite the conceptual problems attending the definition of a drug, a loose but common sense definition is possible for discussing decriminalization, which centrally concerns substances that are consumed recreationally, that is, primarily to produce pleasure, whether or not those substances have other legitimate uses. For the purpose of understanding the current debate, then, recreational drugs can be defined as consumable substances that cross the blood–brain barrier and that (1) can affect mood, cognition, and behavior in pleasurable ways; (2) can be used primarily for recreation, including relaxation, excitement, and pleasurable states generally; and (3) can be used so as to endanger the user and others. Although admittedly loose, this definition covers both legal recreational substances such as ethanol (alcohol), nicotine, and caffeine, and substances that are illegal either per se or if they are not properly prescribed by physicians such as marijuana, cocaine, opiates, heroin, barbiturates, amphetamines, phencyclidine, and the like.

Decriminalization and Criminalization of Drugs

Decriminalization and criminalization are as difficult to define as drug because each includes widely varying legal responses to drug-related activities. Indeed, the debate should properly be characterized as including a wide spectrum of opinions and proposals. The core of decriminalization proposals, however, is the limitation or abolition of present criminal prohibitions of actions related to recreational drug use by competent adults. Some prefer the term legalization to refer to the limitation of criminal prohibitions and penalties. Other, primarily rights-based theorists, believe that state criminal prohibition of recreational drug activities is not prima facie justified, so they prefer the apparently more politically neutral term decriminalization. For ease of exposition, the latter term will be used.

The specific details of particular decriminalization proposals depend on the proponent's position on rights and on the costs and benefits of the proposal compared to the current regime of criminal prohibition. Proponents recognize that some criminal law regulation and substantial civil law regulation will probably be necessary to respond to recreational drugs, but all agree that substantially less use of criminal law is desirable and that it should not be the primary mode of regulation.

The core of criminalization proposals is that the criminal law should be the primary means of regulating recreational drugs, but the proper scope of criminalization is disputed and

 http://dx.doi.org/10.1016/B978-0-08-097086-8.45024-5

virtually all defenders of criminal prohibitions believe that noncriminal means such as education and treatment should also be used. Virtually no proponent of criminalization argues for expanding the scope of criminalization, say, by prohibiting the recreational use of currently legal substances such as alcoholic beverages or by substantially increasing the already serious criminal penalties for drug offenses. The current debate is about limitation, not expansion, and whether criminal law should be the primary mode of regulation.

The Current State of the Decriminalization Debate

The debate about decriminalization has altered substantially in the past decade for a variety of reasons. Although the basic positions have been established for decades, the vast violence and corruption the illegal drug trade produces has caused unprecedented numbers of domestic and foreign politicians and other opinion leaders to call for various forms of decriminalization. Some nations and individual communities have adopted de jure or de facto decriminalization, typically coupled with greater emphasis on public health, and these changes have seemed to succeed. For example, two states in the United States voted in the 2012 elections to decriminalize marijuana and other states have approved marijuana for medical use. Advocacy for decriminalization of marijuana, which is not a particularly dangerous drug, has been considerably more frequent and successful than similar claims for allegedly 'harder' drugs, such as heroin and cocaine.

Many researchers have tried to model or to predict how various forms of decriminalization would specifically affect drug use in particular and society more generally. Most have concluded that the exact effects are very difficult to estimate, but that decriminalization is not a cost-free panacea.

Major strides have been made in understanding the biological basis for addictions. Such understanding typically lends support to treating drug use as the sign of a disorder rather than as a crime.

Harm reduction approaches that use a mix of law enforcement and public health approaches are also familiar, but have gained greater impetus in recent years as various courts and researchers have experimented with apparently successful programs to use public health initiatives and the leverage of the criminal law to reduce the violence associated with the drug trade and drug use. In short, in the United States, criminal law enforcement still represents the primary response to the recreational use of drugs, but the trend in the debate is much more strongly in favor of decriminalization or forms of regulation other than a purely punitive response.

A reasonable speculation in 2013 is that decriminalization 'experiments' and harm reduction policies are likely to increase, especially for marijuana, but criminal law enforcement will remain a major tool.

The Limits of the Criminal Law: The Harm Principle

The state's police power to apprehend, prosecute, convict, and punish citizens is one of the most awesome and probably the most afflictive power it exercises. Infliction of such pain requires substantial justification in liberal democracies that seek to protect individual rights and liberty. Afflictive and expensive criminal regulation should be avoided in favor of less intrusive means unless the harm is great, punishment would be deserved for causing it, and criminal prohibition seems necessary to reduce the level of harm and will not unduly impose on other important interests. Criminal law theorists term these limitations on the state's power to criminalize the 'harm principle.' For example, intentionally inflicting emotional cruelty on others is morally despicable, but such behavior is not criminalized because the harm is considered insufficient to justify criminal punishment and criminalizing such conduct would have other wide negative effects. Socialization by families, religious organizations, and schools is reasonably effective to limit such conduct, and regulating such behavior by criminal law might intrude on protected liberties, such as the right to free speech.

There is little debate about the state's justification for prohibiting and punishing traditional crimes against the person, such as homicide and forcible rape, and against property, such as theft and arson, that cause grievous harm. Although individual liberties are precious, no citizen has a right to kill, rape, steal, or burn the property of others for private advantage and the criminal sanction seems necessary to curb such behavior. Societies can disagree about the scope of appropriate criminalization. For example, there may be reasonable dispute on how much creation of homicidal risk should be necessary to warrant criminal penalties in addition to civil damages or how severely arson should be punished, but the state's power to criminalize great harm to others is uncontroversial.

The harm principle suggests caution before criminalization, however, when the harm is primarily inflicted on oneself, when the harm is primarily moral and not physical, psychological or economic, or when using criminal law to prevent the harm appears to intrude on important rights or appears unnecessary effectively to reduce the harmful behavior. In liberal societies, the right of the state to criminally prohibit actions that harm primarily the actor (so-called legal paternalism) is more controversial than the right to prohibit harm to others because respect for individual liberty and autonomy generally entails that citizens have greater liberty to harm themselves than to harm others. Such liberty is most arguably extensive and the state's right to regulate criminally is most questionable when the threatened harm to self is apparently solely moral and no other harm to self or to others can be discerned. Most liberal theorists reject the state's power to use criminal law solely for the purpose of enhancing the moral perfection of its citizens – so-called legal moralism. Such goals are not the business of the state and should be achieved by other, less intrusive means.

In political and moral regimes that grant the state more authority to regulate individual liberty, both legal paternalism and moralism might be less controversial. For example, theocracies may coherently use the criminal law more extensively than liberal states to achieve paternalistic and moralistic goals. Even within liberal regimes, the permissible scope of paternalism and moralism may vary, although both require more substantial justification than criminalizing harm to others. Consideration of the state's justifiable use of criminal law to regulate recreational drug use, however, must attend to the appropriate limits of state power within a particular

political regime. The remainder of this article assumes that the regime considering decriminalization is liberal.

Recreational Drug Use and Rights

People often assume that there is no right, no liberty interest to use drugs recreationally and, consequently, that the state has appropriate authority to use criminal law to prevent such use. Such an assumption is seldom supported with cogent argument, however, and it is not easy to give compelling moral and political reasons for rejecting such a right.

Sensible discussion must begin with the recognition that people take drugs recreationally because they desire the pleasurable effects produced by consuming substances that alter mood and cognition. It seems clear, however, that the state has no justifiable interest in criminal prohibition simply because the primary or even sole goal of behavior is pleasure or because the behavior involves consumption of a substance that can alter mood or cognition. Many people might consider it wrong to engage in activities solely for pleasure, especially if alteration of mood and cognition were involved and there were some danger of dependence on the activity, but a liberal society does not interfere with a citizen's right to make autonomous choices to engage in such activities. Citizens surely have a prima facie right to seek pleasure for its own sake and it is very difficult to imagine a secular, liberal argument suggesting that such a goal is immoral or harmful per se, even if some danger might sometimes be involved.

For example, suppose that a citizen engages in meditation solely for recreational purposes. No persuasive liberal moral or political theory would justify criminal prohibition of meditation, even if some citizens became dependent on meditating. Recreational drug use involves the consumption of a substance, but it is hard to imagine why the source of the recreation alone should make a difference. Currently, illegal drugs produce pleasure by altering mood and cognition, but so do many legal activities, including meditation, and legal drugs such as caffeine, ethanol (alcohol), and nicotine. The state's right to criminalize alterations of mood and cognition per se is questionable because such alterations are not per se immoral or harmful.

Citizens appear to have a prima facie right to engage in recreational alteration of mood and cognition by drug consumption and the state surely has the burden of justifying criminal prohibition of such recreation by powerful arguments. No right is absolute, however, and the possible right to pursue recreational drug use must yield to a powerful state interest in preventing such use, especially the undoubted state interest in curtailing the threat that drugs will cause substantial harm. Nonetheless, the harm limitation counsels caution before using the criminal law.

Some proponents of decriminalization refer to illegal drug use as a 'crime without a victim' because the person potentially most harmed, the user, in effect consents to the threat. But virtually no action affects only the agent, and recreational drug use sometimes threatens families and communities with economic, psychological, and physical harms. Many of these harms may be paradoxically produced or enhanced by criminal prohibition itself, but many surely are not. Moreover, harms one consents to suffer are nonetheless harms. The often disastrous consequences of various forms of drug addictions certainly harm the person who consents to the risk of becoming addicted by persistently using a substance. The question is whether the harm to others or to self that drugs produce are sufficient to trump the individual's prima facie right to use drugs and thus to warrant criminalization of drug use.

The next section on cost–benefit analysis considers the harms drugs produce, but it must be remembered that liberal societies often permit dangerous behavior in order to protect the right of citizens to pursue their own visions of how life should be lead. Such dangerous behavior is regulated noncriminally, if at all. For example, knowingly following unhealthy dietary habits can severely harm and even kill, and the harm or death can threaten economic, psychological, and physical harms to others. The enormous costs of unhealthy diets are well known, but it is unthinkable in a liberal society to use the criminal law to regulate individual eating habits. To promote the health of the populace, the state can properly regulate the manufacture and sale of food and can impose a duty on manufacturers to warn consumers of potential health risks associated with particular foods. It can even use the criminal law to police egregious failures to comply with such regulations, but it is unthinkable that it would criminally prohibit unsafe eating habits. For another example, consider the immense costs to many users and to society at large that flow from the consumption of ethanol and nicotine. Again, the state can appropriately regulate many aspects of such substance consumption to reduce the consequent harms, including the use of criminal law for egregiously harmful forms of misuse, such as drunk driving. For many reasons, however, importantly including the right to make one's own choices unencumbered by undue state interference, criminal prohibition of the consumption of alcohol and nicotine by the state is considered unwarranted.

If drugs produce great harms per se and no one has a right to use drugs recreationally or if that right is insubstantial at best, then the only question for analysis is whether criminal regulation is justified by the benefits it achieves. But if there is a weighty liberty interest in making choices about how to live one's life, including potentially unwise and dangerous choices about drugs, then the creation of harm is insufficient per se to warrant criminalization. Some dangerous behaviors must be permitted to protect liberty and regulated only by civil remedies, including damages when the harm occurs. Any adequate analysis of decriminalization must therefore include consideration of the strength of the liberty interest and it appears that in liberal societies the right is substantial. Empirical analysis of the consequences of various behaviors under various regulatory regimes is necessary to inform decisions about the appropriate scope of criminalization and decriminalization of drugs, but the question of rights cannot be avoided.

Cost–Benefit Analysis

The outcome of a cost–benefit analysis of decriminalization of drugs will inevitably be indeterminate because much of the data are unavailable, unreliable, or fluctuate and because the costs and benefits of a new regime must be speculative.

Although there have been attempts recently to provide more specific estimates, these, too, are ultimately indeterminate. Debate too often focuses on worst case scenarios that depend on salient but unrepresentative data. Insufficient information and biased misinformation often suggest the wisdom of maintaining the status quo rather than risk making matters worse by changing public policy. Policies such as the criminal prohibition of drugs that arguably fail and that impose great costs, including the infringement of citizens' rights, should be and are debated and cost–benefit analysis plays a crucial role in these debates. Unfortunately, historical and cross-cultural comparisons are of extremely limited value because social variables that vary radically intertemporally within a society and across different societies, immensely affect the consequences of drug use and regulation.

Harms of Drugs and the Benefits of Criminalization

Most currently illegal drugs would create some potential risks to the user and others, even if they were pure, inexpensive, and legal. For example, misuse of drugs can cause addiction and other harmful and well-known health, psychological, and economic effects. People can arguably become addicted to substances other than drugs and to activities such as gambling. Moreover, the concept of addiction is itself problematic. Nonetheless, assume that, for various cultural and biological reasons, most currently illegal drugs have greater addictive or other harmful potential than most other substances and activities.

Much decriminalization debate mistakes the probability and extent of the risks drugs pose. For example, most people who use most drugs recreationally do not become addicted and the moderate recreational use of drugs is not per se dangerous if the drug is pure and properly consumed. Nonetheless, the ease of access to drugs following decriminalization would surely increase the prevalence of use, abuse, and addiction and their further harmful consequences. The harms might be especially great in poorer and minority communities, where the prevalence of drug use is no higher than in other communities, but where the effects have been more devastating. Indeed, some responsible observers believe that decriminalization might effectively destroy poorer and minority communities already ravaged by drug abuse and addiction.

The relation between drugs and other criminal activity and health harms is fraught because it is difficult to disentangle the effects of criminalization itself from the independent effects of drug use. Some drugs, especially if used heavily, can substantially impair judgment, facilitate impulsivity, and have other effects that increase the risk of criminal offending and other dangerous behavior, such as careless driving or sharing needles for intravenous injection. Increased drug use, especially heavy use, will raise the rates of such undesirable behavior.

Criminalization of drugs inhibits use generally by making production, sale, possession, and use more expensive and dangerous and by sending the clearest possible message that drug use is wrong. For example, there may have been both rights-based and consequential reasons to repeal prohibition in the United States, but the data suggest that consumption and consumption-related diseases such as cirrhosis of the liver both decreased when most alcohol production and sale were illegal. Criminalization also helps prevent drug use by minors. Although minors regrettably have access to and consume drugs in a regime of criminalization, ease of access generally would also increase use and abuse among minors.

The use of criminal law to regulate drug use and related harms is obviously not fully successful by any standard and it is immensely expensive, but the proponents of continued criminalization argue that the current regime provides greater benefits than costs and that the unknown benefits, if any, of decriminalization would pale in comparison to the costs of inevitably increased use and abuse.

The Costs of Criminalization

Criminal law enforcement, including imprisonment, is an especially intrusive and expensive form of regulation of any behavior. The cost–benefit critique of criminalization argues that such costs are not outweighed by the benefits because criminal law is powerless to make more than a small dent in the use of drugs and because criminalization itself creates many avoidable harms.

The attempt to eradicate drug use by criminal prohibition cannot fully succeed because large numbers of people want recreational drugs for the pleasure or relief they provide and it is widely recognized that the dangers of drugs are often exaggerated. The criminal law's so-called war on drugs in the United States is fighting a fluctuating but always immense number of citizens, most of whom are not addicts or abusers and whose use does not pose grave danger to society or themselves. It is hard to enforce laws that such large numbers of people wish to violate and that have no immediate and direct complaining victim. Furthermore, public hypocrisy about drugs inevitably undermines law enforcement. Western society is not nearly as monolithically antidrug as many claim, as public policy toward alcohol and nicotine indicates. Given the powerful factors that motivate the desire for drugs, the criminal sanction appears ineffective. The criminal justice system cannot prosecute and imprison more than a tiny fraction of the enormous numbers of people involved in the illegal drug trade unless the justice system massively diverts resources from other undisputed criminal law needs and abandons civil liberties protections. Some believe that criminal enforcement could be applied in more limited cases with greater effect and at lesser cost. If effective, this change would decrease the costs of criminalization, but the vast majority of jurisdictions are not now employing such programs.

The criminal courts of the United States are already clogged with drug cases and the ever-expanding prison population includes an enormous proportion of drug offenders. Even spending vastly more money seemingly will provide only limited benefit. Despite billions spent on drug enforcement each year, undoubted law enforcement successes and the huge numbers of people in prison for drug-related offenses, drugs are still freely available and ever-purer and ever-cheaper. Fluctuations in drug usage appear far more related to major social, cultural, and economic forces than to criminal law enforcement. The limited decrease in the use of criminal law enforcement produces does not seem to justify the gargantuan costs.

Criminalization also threatens its own effectiveness and creates other problems. For example, criminal prohibitions

raise the price on a good or service – the so-called crime tariff – and insure that there will be an endless supply of producers and dealers who seek to realize the monstrous profits to be made through any means necessary, including violence. It also guarantees that many users will be impoverished and driven to a life of further crime simply to support themselves and to obtain drugs. The immense profits facilitate the growth and power of domestic and international organized crime and can be used to corrupt law enforcement, the criminal justice system in general, and both domestic and foreign politicians. Moreover, the consensual nature of drug offenses insures that law enforcement will unwittingly – and sometimes wittingly – use illegal means to enforce drug laws, thus further corrupting law enforcement and the administration of justice and causing disrespect for both. Criminalization decreases the probability that inevitable drug consumption will occur under conditions safest to health. Finally, primary emphasis on criminal law virtually insures that fewer resources will be devoted to investigating and implementing less intrusive and potentially more effective means to reduce the harms drugs cause.

The Benefits of Decriminalization

Specific decriminalization proposals would produce different benefits, but the potential general benefits of decriminalization are the opposites of the costs of criminalization and can be stated easily in the abstract. They include an increase in personal liberty, probable cost savings, decrease in the crime, violence, and corruption that criminalization produces, increased respect for law enforcement, and increased attention to possibly more effective means such as education, treatment, and civil regulation to reduce use and the harms drugs cause. Criminal law would be used only to prohibit particularly dangerous drug-related activities such as drugged driving or selling to minors. Such traditional use of the criminal law would receive broad public support.

Conclusion

Proponents of criminalization sometimes grudgingly concede the problems with the criminal law enforcement approach, but virtually always criticize decriminalization proposals for their abstract or theoretical nature. They fear that decriminalization will produce an administrative, medical, economic, and social tragedy far worse than the current situation, and they ask for highly specific details and guarantees that this will not happen. Proponents of decriminalization recognize that they cannot provide such guarantees, but properly request in return that proponents of criminalization provide the details of how their approach will finally succeed after nearly a century of ever greater expenditures but apparent failure. Neither position appears able to convince the other on theoretical or empirical grounds, but only in recent years has decriminalization been openly debated and a genuine attempt to model the specific effects been begun. Nonetheless, at least in the United States, it appears that the political support to experiment with decriminalization is still weak, except for marijuana, but it is likely to strengthen.

Drugs: Illicit Use and Prevention

Abstract

Illicit drug use spans multiple risk behaviors, from the consumption of substances that are clearly prohibited by law (e.g., heroin, methamphetamine), to the misuse or use of prescription drugs that have a designated medical purpose. In this article, we will discuss the epidemiology of illicit drug use, including definitional issues that are unique to the substance use field, as well as preventative techniques that have been established to combat the varying types of illicit drug use.

Illicit drug use spans multiple risk behaviors, from the consumption of substances that are clearly prohibited by law (e.g., heroin, methamphetamine) to the misuse or use of prescription drugs that have a designated medical purpose. Therefore, a discussion of 'illicit drug use' necessarily groups several distinct types of illicit drug users into one heterogeneous category of 'illicit drug user.' This presents clear obstacles for prevention scientists, as each type of behavior (e.g., prescription drug misuse, marijuana use, stimulant use) is generally targeted differently in prevention and intervention programing. This article will discuss the epidemiology of illicit drug use, including definitional issues that are unique to the substance use field, as well as preventative techniques that have been established to combat the varying types of illicit drug use.

Defining 'Illicit Drug Use'

Illicit drug use includes several classes of amphetamine and amphetamine-like stimulants, cocaine, heroin, other opioids, and cannabis. Prevalence estimates generally defined 'use' as ingestion of any substance during one's lifetime. However, some studies of incidence (or the initiation of substance use) will focus on consumption of a drug within the previous year or month. When evaluating trends of substance use, these distinctions are important details that will often result in differential definitions of use. Substance users are generally categorized into several distinct groups for treatment purposes: users, substance misusers, abusers, and those suffering from physiological dependence (often referred to as addiction).

The blanket term for those who use illicit drugs but do not meet the criteria for misuse are generally referred to as 'users' (*see* Drug Control: International Aspects). This is the lowest risk category of substance users. Illicit drug misusers are persons who may have obtained prescription drugs from a physician for a legitimate purpose; however, they may be using the drugs for reasons other than prescribed, taking the drugs more often than prescribed, or taking too much (or too little) of the substance they were prescribed. This 'misuse' definition applies exclusively to prescription drugs, as there is no legitimate use for illegal (nonprescription) substances. Any illicit substance, including marijuana, prescription drugs, heroin, or other stimulants, may be abused. Abuse is distinguished by maladaptive patterns of substance use, manifesting distress, or impairment on behavior. Finally, dependence, or addiction, is characterized by a series of psychological symptoms including tolerance, withdrawal, drug-seeking behavior, and continued use of a drug despite negative consequences associated with its use. These individuals present the greatest obstacle for treatment purposes, as use of the drug has become a distinctive and routine component of their life, and psychotherapeutics must often be used to counter the effects of addiction on the brain (Center for Substance Abuse Treatment, 2006).

The Epidemiology of Illicit Drug Use

According to the Centers for Disease Control and Prevention, in 2009, 8.7% of youth and adults (over age 12) have used any illicit drug within the past month. The majority of this use is marijuana (6.6%); however, nonmedical use of prescription drugs is increasingly accounting for a larger proportion of illicit drugs consumed in the United States (2.8%) (SAMHSA, 2011). Since 2002, the rate of use for all illicit drugs (marijuana, all illicit drugs, and nonmedical psychotherapeutic drugs) has increased.

The role our social environment plays (e.g., parenting, peer drug use) in changing the trends of illicit drug use has received a great deal of attention from researchers (*see* Opiate Use and Abuse, History of; Drugs, Decriminalization of: Cultural Concerns). For instance, in a large cohort of youth in Germany and the United States, one study reported that changes in drug use in one's peer group was associated with new incidences (or occurrences) of marijuana use (Miller and Miller, 1997). Low socioeconomic position of the family and social network was associated with marijuana use particularly among men; however, women were more likely to begin using marijuana if they have a history of victimization (Miller and Miller, 1997). The influence of drug use in the peer group and family socioeconomic status was linked to heroin and cocaine use (for a review, see Galea et al., 2004). Having family members who use drugs is strongly linked to cocaine use (Burton et al., 1996), and disruption of the family structure has been consistently associated with use of multiple illicit substances (Galea et al., 2004). At the macro level, neighborhood disadvantage has also been associated with incidence of drug use, particularly for cocaine (Crum et al., 1996). Individual-level characteristics are consistently the strongest risk and protective factors for illicit substance use specifically, educational attainment, homelessness (Crum et al., 1996), race (American Indians and African Americans are particularly at risk), and gender (men consistently have higher rates of use than women).

Age of Onset of Illicit Drug Use

There is a considerable amount of evidence identifying (early) age of onset for illicit drug use as being a salient risk factor for subsequent dependence and experimentation with multiple substances (Hawkins et al., 1992; Kandel et al., 1992). For example, studies have reported the rates of lifetime alcohol dependence to be as high as 40% for those who initiated drinking at 14 years of age or younger (Grant and Dawson, 1997). In comparison, Grant and Dawson also reported a 10% lifetime alcohol dependence rate for those who initiated drinking at 20 years of age or older. Research conducted by Substance Abuse and Mental Health Services Administration (SAMHSA) has revealed that younger age cohorts are reporting more types of drugs used in their lifetime (SAMHSA, 1996). In addition, a number of studies have linked early initiation of illicit drug use to a myriad of adverse consequences including social role functioning, impaired ability to make normative developmental transitions from adolescence to adulthood (Newcomb and Bentler, 1988), reduced likelihood for successful marriages, occupational difficulties, and mental health issues (Jutkowitz and Eu, 1994; Hawkins et al., 1992; Robins and Pryzbeck, 1985; Yu and Williford, 1992). More recently, in a large-scale study examining the age of onset of illicit drug use across seven international sites (e.g., Netherlands; United States; Ontario, Canada; Sao Paulo, Brazil; Munich, Germany; Fresno, California; and Mexico City, Mexico), Vega and colleagues (2002) found that age of onset information revealed a temporal ordering of peak onset from alcohol to marijuana to other illicit drugs. Interestingly, the age of onset patterns for illicit drug use were relatively similar across geographical context, although the prevalence rates of use did vary considerably across international sites.

Prevention and Treatment of Illicit Drug Use

Illicit drug use prevention programs have historically been simply a component of larger programs (e.g., alcohol use programs, crime prevention, etc.), rather than the focus of a specific intervention (*see* Drug Control: International Aspects). These programs are generally brief, educational only (rather than interactive), and do not include multiple components (e.g., community mobilization), which have been demonstrated effective in other substance use prevention domains. Because illicit substances have become more available in recent decades, and in many cases, are prescribed by physicians, they pose a unique challenge to prevention scientists due to their perceived safety. Therefore, the problem of illicit drug use has been tackled from several different angles. Several progressive, theoretically informed prevention programs are detailed in the following section.

Theoretical Foundation for Illicit Drug Use Prevention

Primary prevention, or prevention prior to initiation of illicit drug use, generally targets youth during late childhood or early adolescence. This developmental phase is especially critical, as this is the first time in which youth are exposed to drug use, and problem behavior has yet to be present in many cases (Johnson et al., 1987). During this time, school-based interventions are typically delivered using one of three strategies: (1) mass communication or social marketing; (2) psychosocial implementation; or (3) public policy.

Mass communication, more commonly known as social marketing, has been utilized to change public perception about drug use frequency, prevalence, and outcomes (Catford, 2001). These programs are often developed by the target population, using focus groups or key informants. Social marketing campaigns target a specific age group and population and generally tailor their messages to be relatable to the population. These methods have been applied not only to illicit drug use but, more commonly, to alcohol and tobacco use among youth. Social marketing has the potential for a broad impact given advancements in advertising technology and targeted marketing.

Psychosocial models are posited on Bandura's (1977) social learning theory, operating on the assumption that behavior is learned from one's surroundings. Using this philosophy, prevention programing incorporates multiple social dimensions, including the peer group, family, and community. Modeling positive, antidrug use behavior, resistance skills, and normative assumptions about drug use are targeted and reinforced. Role playing is commonly used to reinforce techniques learned in the classroom. Given that perceptions of drug use among one's peers are often severely distorted, these techniques are used to bridge both education and skills training to reinforce the notion that drug use is not a 'normal' behavior.

Similarly, a long line of research has demonstrated that illicit drug use among adolescents is intrinsically linked to their perceptions of their peers who use illicit drugs and/or having friends who report using illicit drugs (Jennings and Akers, 2011). Akers (1977) argues that it is within the social learning process wherein youth acquire their own definitions favorable/unfavorable toward using illicit drugs through social interaction and socialization. For instance, illicit drug use, similar to any type of delinquent behavior, generates either positive (beneficial) or negative (adverse) consequences, which have implications for reinforcement. In this regard, Burgess and Akers (1966) are most well known for their modifications to Sutherland's (1947) original nine propositions of differential association theory. Specifically, Burgess and Akers (1966, pp. 132–145) offered the following seven principles exemplifying the process wherein social learning occurs that have direct implications for illicit drug use:

1. Criminal behavior is learned according to the principles of operant conditioning (reformulation of Sutherland's principles 1 and 8).
2. Criminal behavior is learned both in nonsocial situations that are reinforcing or discriminative and through that social interaction in which the behavior of other persons is reinforcing or discriminative for criminal behavior (reformulation of Sutherland's principle 2).
3. The principal part of the learning of criminal behavior occurs in those groups that comprise the individual's major source of reinforcements (reformulation of Sutherland's principle 3).

4. The learning of criminal behavior, including specific techniques, attitudes, and avoidance procedures, is a function of the effective and available reinforcers, and the existing reinforcement contingencies (reformulation of Sutherland's principle 4).
5. The specific class of behaviors that are learned and their frequency of occurrence are a function of the reinforcers that are effective and available, and the rules or norms by which these reinforcers are applied (reformulation of Sutherland's principle 5).
6. Criminal behavior is a function of norms that are discriminative for criminal behavior, the learning of which takes place when such behavior is more highly reinforced than noncriminal behavior (reformulation of Sutherland's principle 6).
7. The strength of criminal behavior is a direct function of the amount, frequency, and probability of its reinforcement (reformulation of Sutherland's principle 7).

Or stated more explicitly by Akers (1998: p. 50),

> The basic assumption in social learning theory is that the same learning process in a context of social structure, interaction, and situation, produces both conforming and deviant behavior. The difference lies in the direction … [of] the balance of influences on behavior.

> The probability that persons will engage in criminal and deviant behavior is increased and the probability of their conforming to the norm is decreased when they differentially associate with others who commit criminal behavior and espouse definitions favorable to it, are relatively more exposed in-person or symbolically to salient criminal/deviant models, define it as desirable or justified in a situation discriminative for the behavior, and have received in the past and anticipate in the current or future situation relatively greater reward than punishment for the behavior.

Akers and colleagues (1979) provided some of the earliest evidence for social learning's applicability as a theoretical framework to explain illicit drug use, specifically alcohol and marijuana use among adolescents. Subsequent to this initial explicit test, a series of other studies have evidenced and by and large replicated these findings (Krohn et al., 1982, 1985). Similarly, Johnson et al. (1987) investigated the role of peers in adolescent drug use, and their results suggested that associating with peers who exhibited an excess of definitions favorable toward drug use exerted a positive and significant direct effect on the youth's own drug use behavior. Social learning theory, particularly differential association and definitions, has also been shown to have a significant effect on cigarette use (Monroe, 2004), alcohol use, and marijuana use including in cross-cultural studies (Miller et al., 2008).

Similarly, Erikson's stage theory of adolescent development suggests that early adolescents use drugs to mimic what youth perceive to be an 'adult behavior.' The desire for independence and the well-documented 'maturity gap' among early adolescents has led to the development of several 'affective' approaches to illicit drug prevention. Although this affective training is not used by itself, it has been effective when used in conjunction with social resistance skills training and educational components (Johnson et al., 1990).

Public policy has also been implemented in an attempt to deter use of illicit drugs using fear of sanctions (*see* Opiate Use and Abuse, History of). Changes in tobacco policies (specifically, taxes) have been demonstrated as being effective in reducing cigarette smoking; however, relatively little is known about how policy changes influence illicit drug use. Regulation of these drugs provides unique challenges due to the either illegal or controlled nature of illicit substances. A great deal of research is currently in progress to examine the influence of marijuana policy (e.g., decriminalization) on use and negative health outcomes (such as impaired driving and mortality) (*see* Drugs, Decriminalization of: Cultural Concerns). An example of each of these strategies for illicit drug use prevention follows.

Social Marketing

Mass media has been identified as one of the most promising tactics for reducing drug use in future generations. These programs seek to increase knowledge and awareness; however, their potential for inducing behavior change has been questioned (Flay, 1987). Some of these programs are extremely large scale, as the Truth campaign and Just Say No are recognizable to people throughout the United States. These television advertisements are targeted toward youth and seek to educate and deter them from substance initiation.

One example of a social marketing campaign aimed at drug use is the National Youth Anti-Drug Media Campaign (Scheier and Grenard, 2010), often known as 'The Anti-Drug' campaign. This campaign targeted early adolescents and was fairly broad in nature. The advertisements reinforced the notion that drug use would prohibit a person from doing what they want with their life, such as engaging in social activities or professional/educational success. Youth who use drugs are depicted as loners who suffer from several negative effects of drug use. These messages reinforce refusal skills and remind youth that direct refusal is effective in diverting peer pressure. An evaluation of this campaign showed no effect on marijuana use among youth (Scheier and Grenard, 2010).

Psychosocial Intervention

Psychosocial interventions are generally targeted toward youth in primary school, with curricula administered by teachers or other school personnel. These programs teach youth to resist peer pressure, educate youth on the negative consequences of drug use, and provide opportunities to practice situational refusal skills. Programs that have relied primarily on education or scare tactics (for instance, DARE) have largely been unsuccessful; however, hands-on skills training programs have demonstrated success in preventing initiation of illicit drug use.

One example of a well-known school-based psychosocial intervention is known as Life Skills Training (Botvin et al.,

1995). The program included 15 class sessions taught during the 7th grade, with each session focusing on skills training and providing information on resisting social influences toward drug use. Specifically, these sessions used cognitive-behavioral skills training techniques, including self-esteem building, anxiety management, effective communication, positive relationship development, and assertiveness. Each behavior was rehearsed in a peer group, and feedback and reinforcement was provided. Homework assignments were administered to provide additional opportunities for practice. The information provided in educational sessions focused on immediate negative effects of drug use (which may be more salient and resonate with adolescents), rather than long-term, chronic outcomes of drug use. Two short booster sessions were provided (one in 8th grade and another in 9th grade) to reinforce the material learned in the initial intervention. This intervention has been shown to reduce illicit drug use in the intervention group (compared to controls) (Botvin et al., 2000).

Public Policy

Several policies have been enacted in an attempt to combat illicit drug use, including the ongoing 'war on drugs,' zero tolerance policies, and mandatory drug testing (*see* Urban Policy in North America; Crime Policy in the United States). The later has recently been applied in school settings, creating a stir of public interest in drug policy. Several US Supreme Court decisions have upheld the ability of the school district to randomly drug test students (*Veronia School District v. Acton*, 1995; *Board of Education of Independent School District No. 92 of Pottawatomie County v. Earls*, 2002). After these decisions, several anecdotal reports of reductions in drug use by students were reported by teachers and school administrators (Yamaguchi et al., 2009). Rigorous evaluations of the impact of drug testing on schools have not been conducted due to serious methodological difficulties; however, trend analyses have failed to show a reduction in self-reported illicit drug use before and after drug testing was instituted in schools (Yamaguchi et al., 2009).

Multicomponent Interventions

Drug use is not a single-dimensional behavior, meaning that multiple influences might cause someone to initiate drug use. Characteristics of one's parents and parenting style, selected peer groups, key adult role models, mass media, and community policies are all related to drug use. Environmental characteristics, such as access to alcohol and drugs, unsupervised time, and peer pressure further complicate the etiology of illicit drug use. Therefore, a number of prevention programs have been identified as 'multicomponent,' or using more than one of the aforementioned three models to target and prevent illicit drug use among youth.

One example of an effective multicomponent drug use prevention program was implemented in 27 Native American community elementary schools (Schinke et al., 2000). Each school was randomly assigned to one of three arms: (1) cultural content only; (2) cultural content and cognitive-behavioral skills training; and (3) cultural content, cognitive behavioral skills training, and community mobilization, media releases, and community involvement in the intervention. Each of the groups received 'cultural content,' or Native American stories, legends, and values lessons that addressed substance use issues and general health promotion. The cognitive-behavioral skills training condition included 15 one-hour sessions, which trained youth on modeling, resistance, and behavioral refusal skills tailored to substance use prevention. The intervention was tailored to the contemporary Native American culture. The final arm of the intervention included community members, including youth's families, teachers, school guidance counselors, residents, law enforcement officials, and owners/managers of community businesses frequented by youth. Evaluations of this project have shown that the youth who participated in the intervention study had lower rates of tobacco, alcohol, and marijuana use than those who did not receive the cognitive-behavioral intervention. The community intervention arm, however, did not have any additional benefit on substance use compared to the cognitive-behavioral intervention.

Social Learning Theory Interventions

Finally, the principles of social learning theory have been applied to prevention, treatment, and rehabilitation programs as well (Andrews and Bonta, 2003; Cullen et al., 2003). Specifically, applications of these types of programs are generally designed to manipulate definitions/attitudes, associations, group norms, imitation, reinforcement/punishment, discriminative stimuli, conditioning, or other relevant factors that are likely to be associated with deviant behavior generally and substance use more specifically. These programs include: group therapies and self-help programs; peer programs; gang interventions; family and school programs; teenage drug, alcohol, and delinquency prevention/education programs; and other private and public programs in correctional, treatment, and community facilities and programs. Akers and Sellers (2009) have reviewed a number of these intervention and prevention strategies, and in this vein, they note that while large effect sizes are often not demonstrated for the importance of social learning principles, the literature is relatively consistent in reporting that among prevention and intervention programs that employ social learning principles these effects are typically larger than prevention and intervention programs that utilize alternative principles and strategies other than social learning. The following quotes from respected researchers in the field best summarize the effects of preventions and interventions that emphasize social learning principles:

> [R]esearch on correctional programs supplies strong and consistent support for theories – such as differential association/social learning theory – that link offending to antisocial associations and to the internalization of antisocial values. …'[C]ognitive-behavioral' programs tend to achieve higher reductions in recidivism than other treatment modalities. … These programs

specifically target for change antisocial values and crime-excusing rationalizations, they reward prosocial attitudes and behavior, and they seek to isolate offenders from pro-criminal associations. (Cullen et al., 2003: p. 353)

[The relative success of cognitive-behavioral programs is consistent with] "social learning theory [that] is broader than behavioral reinforcement theory because it includes as variables cognition, verbalization, and social modeling to explain (and to change) behavior patterns." (Pearson et al., 2002: p. 480)

The use of cognitive-behavioral interventions is consistent with the conclusion of other meta-analyses that interventions based on social learning theory are particularly effective (Lösel, 1995). Social learning theory asserts that behavior is learned through several processes, including modeling, imitation, and differential reinforcement (Bandura, 1979). He is also likely to associate with people who encourage his violent behavior (differential association). Cognitions that support specific behaviors are known as "definitions" (Akers, 1985). Definitions, then, could be seen as one form of the problematic cognitions that the therapist needs to address (Ellis and Sowers, 2001: pp. 91–92; emphasis in original).

Conclusions

In conclusion, the need for complex, multicomponent interventions and prevention programing to target illicit drug use is clear. The vast majority of drug users will first experiment with substances in early adolescence (ages 11–14); therefore, prevention programing must begin in elementary and primary schools. The etiology of illicit drug use is complex and multidimensional; therefore, programs that have addressed only one component have been largely unsuccessful in preventing drug use initiation. For instance, a program might address drug-using peers; however, if a parent uses cocaine, these unaddressed parental influences will continue to reinforce pro-drug behavior and intentions. Overall, illicit drug use continues to pose a growing problem to public health professionals, policy makers, and prevention scientists.

Abstract

This article begins with a definition of drug use, followed by a consideration of the factors that make this particular class of behavior unique. Distinctions are made among various classes of drugs, based on their legal status and social acceptability. The typical stages of involvement in drugs are described, distinctions among use, abuse, and dependence are made, and polydrug use is discussed. Finally, consideration is given to various other psychosocial correlates of use, including particular attitudes and beliefs, as well as the individual's level of integration into society in general, and into certain key institutions in particular.

Psychoactive Drugs

The use of psychoactive drugs is not a new phenomenon. There are numerous adverse consequences of drug use, the most important of which is drug abuse. The term 'drugs,' which is commonly used today, is a shorthand for 'psychoactive drugs,' i.e., compounds or substances which alter the neurological functioning and/or structure of the organism in such a way as to directly influence perception, mood, consciousness, and/or energy levels. There are many compounds that have such effects, ranging from those occurring naturally in plants (e.g., cocaine, caffeine, nicotine, cannabis, opium, psilocybin) and natural processes (fermentation of fruit and other plant products containing carbohydrates, yielding alcohol) to compounds that are synthesized (e.g., benzodiazepines, amphetamines, Lysergic acid diethylamide (LSD), 'ecstasy,' and 1-(1-phenylcyclohexyl)piperidine (PCP)).

Distinguishing Characteristics of Drug-Using Behaviors

There is one central characteristic that distinguishes psychoactive drug use from most other classes of behavior. Drugs influence the neurological system directly and provide pleasure or other forms of reinforcement (Koob and Nestler, 1997). In essence, drug use involves a shortcut to the pleasure centers of the brain. As a result of this shortcut, drug-using behavior can come to take a higher position in the hierarchy of needs displacing many behaviors that are adaptive such as eating, forming appropriate bonds to family and community, working, or performing well academically. It can also disrupt fundamental psychological processes essential to performing a wide range of other behaviors or tasks by altering or impeding perception, memory, decision making, motivation, and energy levels. Second, the direct reinforcing properties of psychoactive drugs on the neurotransmitters in the brain can alter the structure and function of the neurological system itself, such that a need is created for the drug in order for the individual to attain what had previously been a normal level of neurological functioning (Everitt and Robbins, 2005; Koob and Nestler, 1997). In other words, the user can become dependent on or addicted to the drug; thus, the underlying motivation for using a drug can shift quite dramatically from what might have motivated use at earlier stages of involvement.

Illicit versus Licit Drug Use

There are many psychosocial determinants of the use of drugs, two of the most important of which are the legal and normative status of particular substance-using behaviors in the society. The primary focus in this article will be on psychoactive substances, the use of which is considered illicit in most societies. Tobacco and alcohol are generally licit to use and legal to possess; but because they are dealt with at some length in other entries, they will receive only very general treatment here. It should be noted, however, that even the use of alcohol and tobacco by people under certain ages is considered illegal and illicit. Three general social classifications of drugs will be distinguished, and the importance of their classification considered: psychotherapeutic drugs, legal drugs, and illegal drugs.

Psychotherapeutic Drugs

Certain drugs can be either licit or illicit to use, depending on the conditions under which use occurs; and they can be legal or illegal to possess, depending on how they have been obtained. A number of drugs have medical applications, so their use is considered as legitimate for the medically supervised therapeutic treatment of particular conditions. These drugs include tranquilizers (most of which are benzodiazepines, used to alleviate anxiety), sedatives (most of which are barbiturates, used to induce sleep), amphetamines (used to treat hyperactivity disorders), and various opium derivatives and their synthetic analogs (used to control pain, coughing, and diarrhea). All of these drugs have regulated access, through the requirements of a doctor's prescription and pharmacy dispensation. However, the sale, possession, or the use of these substances outside of prescribed medical regimen is considered illicit and illegal, in part because all of these drugs have the potential to produce dependence in the user; and dependence is presumed to be more likely to develop under conditions of unsupervised use.

The Legal Drugs

Certain drugs have emerged as legitimate to use in most societies outside of any medical regimen and without any therapeutic purpose, usually because at the time of their emergence, they are presumed to be safe. These include alcohol, nicotine, and caffeine. Most of these substances have been in fairly widespread use for some time in different cultures. Use of these drugs is widespread not only because their use is legally and normatively accepted but also because their legal status allows those who sell them to engage in massive advertising and promotional campaigns aimed at encouraging and facilitating consumption of the drug. Although there have been some concerns in the past about the health and societal consequences of alcohol and tobacco, such concerns increased considerably over the course of the twentieth century. This has led to increased stigmatization of their use and legal controls on their sale and distribution.

The Illegal Drugs

In the twentieth century most other drugs have been deemed illegal and illicit to use, possess, or sell in most societies. This illegal status is based largely on the negative impact on the functioning of the individual, family, and/or larger society. Various international treaties have had the effect of making the legal status of these drugs fairly homogenous throughout the world. The 1961 Single Convention outlawed plant-based substances such as derivatives of coca, marijuana, and opium (United Nations, 1972). Later the 1971 Convention made synthetic drugs such as LSD and MDNA illegal while the 1988 Convention made the trafficking of these drugs illegal (United Nations, 1971, 1988).

The boundaries of social legitimacy and illegality of the use of various drugs are themselves subject to change, as knowledge accumulates about the effects of the drugs and also about the effects of the control mechanisms intended to control their use. Most recently, as the consequences and side effects of substances known as 'head shop' products, 'legal highs,' or 'designer drugs' became apparent many countries have reclassified these drugs as illegal as much as possible (UNODC, 2013). Conversely, there is an ongoing vigorous policy debate over the possible reclassification of currently illegal marijuana. Over the past few years a number of countries including Australia, Spain, and the United States have shifted away from prohibition with an introduction of a quasilegal position for marijuana (Caulkins et al., 2012). One of the major reasons given by those who oppose the legalization of marijuana or other illegal drugs is that legalizing these drugs would unleash powerful marketing forces similar to alcohol and tobacco (Inciardi and McBride, 1991). Stemming from this some argue that reclassification would destigmatize marijuana making it seem less dangerous. Alongside increased access this would result in higher prevalence of use (Roffman, 2013).

Stages of Involvement

The research literature on substance use has distinguished a number of stages of involvement with a drug (Clayton, 1992). In general, the stages of use of a drug can be described as abstention, initiation, continuation, progression, dependence, and relapse. In addition, the cessation of use can occur after initiation, progression, dependence, or relapse. It is well recognized that addiction is a chronic condition in which relapse generally occurs a number of times (DiClemente et al., 2011).

The notion of stages of involvement applies not only to individual drugs, but also across drugs. Drug use typically begins with more socially acceptable 'Gate way drugs' such as alcohol and tobacco (Kirby and Barry, 2012). The use of certain substances tends to precede the use of other ones with a high degree of regularity (Kandel, 1975; Kandel et al., 1992). Marijuana use, for example, is usually preceded by the initiation of cigarette smoking, and the two behaviors remain highly correlated at later ages. Alcohol use also tends to precede the use of tobacco and marijuana; and marijuana use, in turn, usually precedes use of most of the so-called 'hard' drugs like stimulants, opiates, and hallucinogens (Kirby and Barry, 2012). The regularity of this pattern of progressive involvement has led to work aimed at predicting specific details of these transitions.

Psychiatric researchers have been most concerned with defining, understanding, and intervening in the later stages of involvement. Explaining progression in the earlier stages of involvement, and trying to intervene in that progression has fallen largely to the social sciences. Though many social scientists who work in this field are informally called epidemiologists or etiologists, in fact they have tended to come mostly from psychology (including social, clinical, counseling, and community psychology), sociology, social work, anthropology, and, more recently, public health and economics. Two very general fields have evolved here: first, the study of the natural phenomena and second, the development of interventions (e.g., education, prevention, persuasive communication). Because prevention is the subject of other entries, it is mentioned here only to note that the scientists and program developers in prevention tend to have quite similar disciplinary backgrounds and theoretical underpinnings as those who work on the etiology and epidemiology of substance use. Social learning theory has been widely adopted in all of these subareas, for instance.

Initial Trajectory of Drug Use

There are a great many individual risk factors for psychoactive drug use (e.g., Clayton et al., 1995; Glantz and Pickens, 1992). Substance use disproportionately occurs among those from socioeconomically deprived backgrounds (Redonnet et al., 2012). Some of the strongest risk factors for substance use among youths and young adults have to do with their degree of attachment to, or integration with, key institutions in society. At the broadest level, deviance from societal norms in general, as reflected by delinquent behavior, is a strong correlate of virtually all forms of illicit drug use (including underage drinking and smoking). It should not be surprising that one class of illicit behaviors (drug use) correlates strongly with a range of other illicit behaviors. It simply means that people who are willing to violate legal and normative constraints in

one domain of behavior are willing to do so in others, as well. One result of this fact is that the correlates and determinants of the various 'problem behaviors' among youth tend to be the same. Among them are attachments to various other institutions, but in particular the family, school, and church (Brook et al., 1990).

Young people who have a low degree of attachment or 'bonding' to school – meaning that they are not performing well, do not like school, and may frequently be absent – are at particular risk of involvement with illicit drug use. For example, those who drop out of school early, are more likely to become involved in substance use (McCaffrey et al., 2010).

Use, Abuse, and Dependence

One important distinction in psychosocial aspects of drugs has been between use, abuse, and dependence. Much debate and controversy surrounds these terms, and exactly what defines use, abuse, and dependence with further complications arising when it comes to operationalizing these distinctions.

In theory, the distinction lies in whether the drug-using behavior has reached the stage at which it is adversely affecting the normal functioning and well-being of the individual and, therefore, has become 'abuse.' Is the individual's drug use disrupting normal emotional, cognitive, social, or work functioning, including school performance for those in school, or is it endangering physical health? Is it interfering with the user's functioning in key social roles, such as spouse, parent, child, friend, student, worker, and citizen?

Some research on the reasons adolescents give for using various drugs may help to elucidate the theoretical distinction between use and abuse (Johnston and O'Malley, 1986). Young people who have used a drug only once or twice usually give as their primary reason curiosity, 'to see what it was like.' Those who have used drugs only on a reasonably limited number of occasions, but have gone beyond experimentation, most often mention reasons such as 'to feel good or get high' or 'to have a good time with my friends,' which might be called social and recreational reasons for use.

However, those who have used a drug with some frequency start to mention what might be called psychological-coping motives for their use, e.g., 'to get through the day,' 'to get away from my problems,' 'because of anger or frustration,' 'to relax or relieve tension.' Therefore, abuse emerges when use of the drug continues regardless of recurrent social, occupational, physical, or psychological problems such as psychological coping (WHO, 1994).

In general, dependence is seen to emerge when one needs something to feel good, function, or survive (WHO, 1994). Substance dependence is defined by the World Health Organization as "A cluster of physiological, behavioral, and cognitive phenomena in which the use of a substance or a class of substances takes on a much higher priority for a given individual than other behaviors that once had greater value" (Isaac et al., 1994). This includes both, physical and psychological elements. For dependence to be diagnosed, at least three symptoms such as craving, withdrawal symptoms, increased tolerance, loss of control of drug use, neglect of other interests, and the persistent use despite clear evidence of harmful consequences need to be present together over the previous 12 months (Janca et al., 1994). In 2012, 10–13% of all drug users worldwide were dependent users (UNODC, 2013).

Polydrug Use

Polydrug use means using two or more drugs in combination, using one drug to counteract the effects (or the after effects) of another or using different drugs at different times over a short period of days or weeks. Most illegal drug users are polydrug users. Using a single psychoactive drug can be dangerous; using more than one significantly increases the risks. Polydrug use combinations could increase the likelihood of physical or psychological harm (Forsyth, 1996; Earleywine and Newcomb, 1997; Feigelman et al., 1998; Riley et al., 2001) and difficulties in engaging in treatment (John et al., 2001). In particular, if two drugs of the same type, such as the depressants heroin and alcohol, are used together there are greatly increased risks of accidents, overdose, and death. Other common, dangerous drug combinations include cannabis with alcohol, ecstasy with alcohol, heroin with sedatives, and amphetamines with sedatives. There are also challenges in developing effective treatment approaches for polydrug users because of the different psychological and physiological effects of different substances (Kenna et al., 2007).

Attitudes and Beliefs About Drugs

Social Connotations of Use

One of the many influences on substance use is the symbolic meaning the individual sees it as having within society at large or within various social circles. It is obvious that cigarettes and alcohol have acquired certain associations in peoples' minds as a result of intentional manipulation through advertising. Less obvious perhaps is the fact that even unadvertised substances acquire social connotations, and that these may change considerably over time. The high degree of association of marijuana and LSD came to have with the counterculture already has been mentioned. When cocaine use first started to grow in the late seventies, it was very expensive and thus was used disproportionately by the rich and sometimes famous. As a result it acquired a certain caché that made its use more desirable to many, whereas a number of other drugs, like heroin, were more associated with marginal groups and the less affluent. It seems likely that adolescents come to see inhalants as kids' drug as they get older, and that their use declines as a result.

Perceived Risk

Whether drugs are seen as dangerous to the user or to others can also affect how they are seen more generally. The dramatically lowered social acceptability of tobacco over the past two decades illustrates this point. As smoking came to be seen as carrying high risk of morbidity and mortality, it became a less popular behavior, primarily with adults. Social norms, and regulations and laws, shifted quite dramatically. Taxes were

used to increase the price of tobacco, mass media campaigns were launched, and as the evidence grew of the adverse effects on others from their passive exposure to tobacco smoke, smoking in many public places, once an assured right, became a frequently denied privilege. These various steps have led to reduced prevalence of smoking as well as reduced initiation of smoking. Policies which targeted work places have also led to reduced consumption and increased tobacco cessation (Wilson et al., 2012). A similar thing happened with alcohol, when the many adverse effects of drinking came to be more widely recognized. This was illustrated through the impact of price hikes on alcohol through taxation which led to a decrease in consumption in addiction to lower levels of heavy drinking (Wagenaar et al., 2009).

A number of the illicit drugs have also had considerable transformations in their social acceptability, as their adverse consequences were documented and made widely known. In the late 1970s, as cocaine use became more widespread, there was little convincing evidence of adverse effects, as 'experts' proclaimed that cocaine was neither lethal nor addictive. The evidence eventually accumulated to prove them wrong, but it took some years because there turned out to be a long lag-time on average between the initiation of use and the development of dependency and other serious problems. Researchers at the University of Michigan have demonstrated the importance of perceived risk as a determinant of trends not only in cocaine use, but also in the use of marijuana and other drugs (Bachman et al., 1998; Johnston et al., 2000). Among other things they have shown that a turnaround in the aggregate-level perceived risk associated with a drug by adolescents often presages a turnaround in actual use a year later.

Research Traditions

Many subareas of research on drugs have evolved, particularly in the past 40–50 years. These include etiology, epidemiology, neurology, psychopharmacology, molecular biology, prevention, and treatment. The psychiatric tradition in epidemiology and treatment has emphasized accurately diagnosing and effectively assigning treatment regimens to individual cases. The other social sciences have looked more at drug use in the normal population, with an emphasis on causes, correlates, and consequences. A number of large nationally representative epidemiological studies have been conducted with a focus on drug use. These include the National Comorbidity Survey Replication (Kessler et al., 2004), the National Epidemiologic Survey on Alcohol and Related Conditions (NESARC) (Grant et al., 2004), as well as the National Survey on Drug Use and Health (NSDUH) (SAMHSA, 2011).

The fact that addiction has long been conceptualized as a disease within certain scientific circles has led to terminology that is medical in nature in defining the subfields of research (e.g., epidemiology, etiology, prevention, treatment). In fact, Alan Leshner, the current director of the National Institute on Drug Abuse, has asserted that drug addiction is a disease of the brain, evidenced by lasting structural and functional changes in the brain induced by drug use, but that drug use short of addiction is a preventable behavior (Leshner, 1999).

The importance of the disease concept, for which there is increasing neurological evidence, is that it implies that drug dependence should be responded to as more than just a moral failing. It implies that dependent users have important changes in their neurotransmitter systems that reduce to a considerable degree the extent to which they have reasonable control over their drug-using behavior.

Three US Nationally representative studies of adults include the National Co-morbidity Survey Replication (Kessler et al., 2004), the NESARC (Grant et al., 2004), and the NSDUH (SAMHSA, 2011; Merikangas and McClair, 2012).

Future Directions

It has become increasingly clear that both licit and illicit substance use must be viewed in terms of age, period, and cohort effects, since all three different types of change have been observed and documented (Johnson and Gerstein, 2000; Johnston et al., 2000). The factors explaining each of these three types of change are likely to be different, as is the timing of their action. The continual emergence of new illicit drugs onto the scene will yield new drug-taking phenomena to be understood and influenced. Undoubtedly more will be learned about the neurological action and effects of the many drugs, which may well change the importance of certain psychosocial factors, such as perceived risk, in determining their use.

The field is extremely multifaceted as has been illustrated here. The number of drugs is large and growing, and they have a wide range of psychological and physical effects. There are many levels of social and psychological determinants of this group of behaviors, ranging from legal, moral, normative, and religious, to neurological, psychological, sociological, political, and economic. (Because drugs are commodities, market considerations also influence use.) Further, drug use is the object of many social interventions, from various forms of education and persuasion to treatment. Thus, despite the considerable resources currently going into research on the determinants of drug use, it is clear that there will remain a great deal to be learned about this unique domain of behavior for some time to come.

Abstract

This essay presents a brief survey of W. E. B. Du Bois' (1868–1963) long life and prolific scholarship. It includes details of his education, travel, and changing political opinions. A selection of his many publications is discussed and there are some speculations about the intellectual influences from both Europe and North America that guided his thinking. His career inside and outside the academy is considered along with his continuing impact on scholarly writing in the social sciences and the humanities.

William Edward Burghardt Du Bois was born in Great Barrington, Massachusetts on February 23, 1868. Ninety-five years later, having renounced his citizenship of the USA, he died an exile in Accra, the capital of the newly decolonized republic of Ghana on April 29, 1963. An unorthodox and multidimensional career had unfolded between these two events. An unwavering devotion to the cause of human progress underpinned Du Bois' cosmopolitan life that was also characterized by bold shifts in ideological outlook. He moved through pragmatism, elitism, socialism, nationalism, and several versions of Pan Africanism in an idiosyncratic, but always thoughtful sequence that terminated amidst the gloom of the Cold War when the old savant, aged 93 and deprived by his government of the means to travel freely, applied to join the Communist Party of the USA and then fled the land of his birth.

Du Bois had been identified as an outstanding student at an early age. After completing high school in Massachusetts, he continued his studies initially at Fisk University in Nashville. When he entered the college in 1885, it was a haven lodged in a bitterly segregated world still resonating with the destructive energies released by civil war. Life there, confined within what he called the veil of color, was a very different proposition from anything that Du Bois had experienced in the New England environment that had nurtured him. It was there that he discovered and wholeheartedly embraced the black cultures of the American South that he encountered inside the historic college, and discovered in more intense and ambiguous forms while working as a school teacher in rural Tennessee during the summer vacations. He concluded his studies at Fisk in 1888, choosing the German Reich's Chancellor Otto Von Bismarck as the topical subject of his oration at the college graduation ceremony.

In fulfillment of a childhood dream, and in recognition of the opportunities it would bring, Du Bois moved on to continue his education at Harvard later the same year. Among other classes, he studied philosophy with William James, who would become a friend, and read Kant with George Santayana. He took economics under Frank Taussig and history with Albert Bushnell Hart who helped to pilot his career through numerous institutional obstacles. After graduating *cum laude* in Philosophy in 1890, he applied to pursue postgraduate study in Political Science and gained an MA degree in 1891. It was at this point that Du Bois began to seek ways to continue his education in Europe. Financial support was difficult to find but in 1892 he was eventually rewarded with a year-long grant to study in Germany. Later that year, he entered Friedrich-Wilhelm III University in Berlin where his teachers included Gustav Von Schmoller, Adolf Wagner, and Heinrich Von Treitschke. It was also there that he first encountered Max Weber and Georg Simmel.

Du Bois attended several meetings of the Social Democratic Party (SPD) while living in Berlin. He had been working towards a German doctorate in economics but, to his disappointment, was denied the degree on the grounds that he had been registered at the university for an insufficient length of time. After extensive travel in Europe he returned to the corrupting provincialism of 'nigger-hating America' to complete his thesis in Harvard's History department in 1895. Shortly afterwards, he became the first black person to receive the Ph.D. degree from that University, but as a result of this success was hugely overqualified for the limited professional opportunities available to him in a world that could not concede the intellectual capacity of 'the Negro' and consequently viewed him as something of a curiosity.

He eventually found a position at Wilberforce College in Ohio where he taught Classics, Greek, and English. His growing interest in Sociology was manifest in some unsuccessful attempts to have the new discipline added to the curriculum. He married Nina Gomer, who had been a Wilberforce student, in 1896 and, later that year, his first book *The Suppression of the African Slave Trade to the United States of America 1638–1870* (1896) was published to very favorable reviews. This welcome development boosted Du Bois' career prospects and enabled him to move to the University of Pennsylvania, where he was employed to produce a groundbreaking sociological study of Philadelphia's black population. Work on that project would continue after he accepted a Professorship of Economics and History at Atlanta University the following year.

This new post provided an institutional platform from which Du Bois organized an ambitious program of sociological investigations into various aspects of black life in the USA. It resulted in a flow of major publications between 1898 and 1914. His substantial empirical study of Philadelphia was published under the title *The Philadelphia Negro* in 1899; it was given a distinctive character by well-developed interests in economics and comparative history. It is rightly remembered as a landmark publication: the first academic monograph to

 http://dx.doi.org/10.1016/B978-0-08-097086-8.61025-5

consider the life of an American black community in depth. The Du Bois household was struck by calamity when Burghardt, their two year-old son, died of diphtheria in May 1899. This tragedy seems to have led to estrangement between Du Bois and his wife. However, it combined with his growing academic and political ambitions to endow an elegiac and sometimes melancholy tone in his next book: *The Souls of Black Folk* published in 1903. This was a remarkable, multivoiced collection of his essays, autobiographical reflections, and fiction. It made him a leader of black Americans.

Du Bois' commitment to resolutely open-ended, liberal, and humanist education which would nourish the needs and responsibilities of a black elite destined for leadership at both local and global levels, brought him into conflict with the more modest and practically oriented educational proposals that were being advocated by Booker T. Washington and were on show at his Tuskeegee Institute. This national debate, which exposed the molten core of black America's political and economic marginality, resulted in Du Bois leaving Atlanta University to pursue a new para-academic career as a writer, editor, and activist based in the North. In 1910 the newly formed National Association for the Advancement of Colored People (NAACP) hired him as Director of Publications and Research. He was the founding editor of, and a prolific contributor to, the organization's influential and dynamic monthly magazine *The Crisis*, a post he would hold until 1934. His first novel, *The Silver Fleece* was published in 1911, the same year that he attended the Universal Races Congress organized in London by the English Ethical Culture movement.

The death of Booker T. Washington and the advent of the 1914–18 war transformed the political conditions in which Du Bois argued for the equality of black Americans and indicted the catastrophic impact of racism on the American polity stratified by color. Though he never completed a proposed volume on the experience of African-Americans during the war, the immediate aftermath of the conflict provided the impetus for the first of several Pan African congresses, which was held in Paris in 1919. After the war, Du Bois' voice was raised against America's failure to recognize its black citizens and in opposition to the gross violence that greeted the returning soldiers. He was severely critical of the more populist and militaristic forms of Black Nationalism associated with Marcus Garvey's United Negro Improvement Association (UNIA) which was growing in importance as the influence of the NAACP diminished.

Du Bois' cosmopolitan outlook and the breadth of his published work made him a pivotal figure among the younger writers, artists, and thinkers who led the artistic and literary movement known as the Harlem Renaissance. He contributed a memorable essay to *The New Negro* anthology, edited by the philosopher Alain Locke, that defined this important cultural departure but conflict soon followed with some of the younger writers, who were regarded by Du Bois as insufficiently attentive to their world-historic political responsibilities. *Dark Princess*, a vibrant political novel that concerns a grand planetary alliance of peoples of color against imperialism and colonialism and which was identified by Du Bois as his own favorite among his many books, was published in 1928.

The thirties saw Du Bois renewing his interest in Marxism and developing an original and complex critique of Marx's political theory. This striking synthesis was elaborated in a monumental historical study: *Black Reconstruction In America* (1935). The first of his several autobiographical volumes appeared in 1940. Du Bois rejoined the NAACP as their director of special research in 1944. He was sacked four years later after yet another bout of political disagreements, this time resulting from his intermittent affiliation to communist causes that the utterly respectable and sometimes conservative organization was unable to tolerate. Anti-colonialist and anti-capitalist commitments led Du Bois into further battles with the US government. In 1951 he was arrested and charged with the crime of operating as an unregistered agent of a foreign power. The charges were eventually dismissed but this unhappy experience galvanized him in support for the Soviet bloc. This phase of his life was explored in yet another book *In Battle for Peace: The Story of My Eighty-Third Birthday* (1952).

Du Bois' Scientific Contribution

Du Bois was the first sociologist of the American South. He articulated the complexities of African-American life in comparaive and historical terms that owed much to his multidisciplinary training. He placed sociological reason at the disposal of black Americans' freedom struggles and sowed the seeds that would bear fruit in the mid-twentieth century legal judgements that cited later sociological studies in support of desegregation. His own timely empirical contributions, particularly *The Philadelphia Negro* (1899) were also important because they replaced top-heavy theoretical speculation with an honest blend of theory with practical innovations in research technique. Guided as much by Schmoller as by the spirit of Charles Booth, Du Bois was also the first American social scientist to make empirical research the pivot of an investigation. His investment in the power of properly scientific sociology as a stimulus for governmental intervention and the pursuit of democracy unmarked by racial categories was considerable; however his faith in progress was neither simplistic nor naïve. Sociology was obviously indispensable but it was also insufficient. Its hard-won truths had to be communicated in several tongues, and made accessible to the widest possible audience. But more than this, Du Bois' achievements suggested that sociology was always at its most eloquent when supplemented and enhanced by the power of poetry.

The Contemporary Influence

In addition to his accomplishments as a distinguished social scientist Du Bois is still remembered as an essayist, editor, novelist, historian, and political leader. The breadth of his intellectual interests and the skill with which he turned them into a host of compelling written material in several distinct disciplines and styles made him the dominant African-American thinker of the twentieth century. Close to the aftermath of slavery and against the expectations of those who had judged 'Negroes' to be incapable of higher learning, his extraordinary work boldly redefined America's racial hierarchy as intrinsic to the incomplete workings of American democracy. In making that unpalatable argument in potent language which was both scholarly and poetic, Du Bois created a black

intelligentsia which understood itself and its historical and sociological predicament in terms he had specified. His exceptional scholarly insights were articulated in a prolific output that continued throughout his long life. All of this work was characterized by a double achievement to match the double consciousness from which it grew – a sense of black intellectuals caught, or as he put it 'imprisoned,' within the folds of European civilization developing interests of their own distinct from those of the black poor.

He transformedunderstanding of African-American history and society while supplying the intellectual cornerstones for new varieties of critical and oppositional consciousness that could move beyond the task of defending America's black communities as they emerged from the twilight of slavery. In articulating an especially rigorous, energetic, and durable brand of dissident intellectual work, Du Bois not only provided solid foundations for the scholarly study of racism, he enabled his many successors to challenge white supremacy in the world ofideas, and provided important conceptual and historical resources for anticolonial movements worldwide.

Abstract

René Jules Dubos enjoyed national acclaim as a medical researcher, author, and environmentalist during the middle third of the twentieth century. Trained first as an agricultural engineer at the French National School of Agronomy, Dubos moved to the USA in 1924 to study soil microbiology at Rutgers University and the New Jersey Agricultural Experiment Station. After completing his doctorate in 1927, he joined the medical research staff at the Rockefeller Institute for Medical Research. Dubos developed the first clinically useful antibiotic from a soil microbe in 1939. This discovery ushered in the era of antibiotic wonder drugs. Although Dubos continued doing medical research until his retirement from Rockefeller University in 1971, he was better known after the 1950s for his promotion of an ecological model of disease and as an elder statesman of the US environmental movement.

René Jules Dubos, the French-American microbiologist, medical researcher, environmentalist, and Pulitzer-prize-winning author, was born in Saint-Brice-sous-Fôret, France on February 20, 1901. He was the eldest son of Georgesand Adeline DeBloëdt Dubos, proprietors of a series of small butcher shops. Two years after his birth, the Dubos family moved to neighboring Hénonville, a small agricultural village in the Île de France region 50 miles north of Paris. René Dubos spent the next dozen years of his life there exploring the French countryside, reading avidly, and excelling as a student at *l'ecole communale d'Hénonville*, the local one-room primary school. Encouraged by his mother to pursue a scholarly career, he dreamed of attending France's distinguished schools of higher learning. The family moved to Paris in 1914. Dubos won a fellowship in 1915 to attend the *Collège Chaptal*, part of the French secondary school system. His father's untimely death at the conclusion of World War I, his family's concomitant financial difficulties, and his own periodic bouts with poor health resulting from an early battle with rheumatic fever, however, prevented René Dubos from studying to become a historian, his first choice among academic careers. Instead, he gained admission in 1919 to the *Institut National Agronomique* (INA), France's National School of Agronomy.

Although many graduates of the INA pursued careers in scientific agricultural research, Dubos disliked laboratory work. Instead, he accepted a fellowship from the French government of Indochina to study at the *Institut National d'Agronomie Coloniale*, where he prepared for a position as a colonial administrator. However, the colonial government revoked its offer of employment at the conclusion of the training program when Dubos failed a physical examination. Having few alternatives, Dubos accepted an editorial position at *l'Institut International d'Agriculture* in Rome, where he abstracted technical articles for publication in the *Journal of International Agricultural Intelligence.* While in Rome, Dubos experienced a change of heart regarding his career plans. Inspired by an argument made in an article by the Russian agricultural bacteriologist, Sergei Winogradsky, Dubos reconsidered his decision to steer clear of laboratory research. In this article, Winogradsky encouraged his colleagues to reject pure culture techniques in favor of studies that more accurately monitored soil microbes in their natural environments. This more ecological approach to microbial investigation appealed to Dubos because it emphasized themes familiar to him from the training he had received as an agricultural engineer in Paris. Dubos gained the opportunity to study soil microbes himself when, at the 1924 International Congress of Soil Science, Jacob Lipman of the New Jersey Agricultural Experiment Station invited the young Frenchman to study soil microbiology at his institution. Dubos accepted the offer, sailed to the USA, and spent the next three years in a doctoral program under the direction of Selman Waksman at Rutgers University and the New Jersey Agricultural Experiment Station.

Soon after completing his Ph.D. in soil microbiology, Dubos received an unusual and compelling offer to join the research team of Oswald Avery, an immunochemist at the Rockefeller Institute for Medical Research. Few agricultural researchers received an opportunity to apply their skills to medical research in the 1920s, particularly at the nation's most prestigious medical research institution, but Dubos's doctoral research on cellulose decomposition filled a specific need in the Avery laboratory. For years, Avery's laboratory group had tried unsuccessfully to strip the polysaccharide coating from the type III pneumococcus responsible for lobar pneumonia. Avery theorized that the coating protected the bacillus from the human body's natural defenses. Dubos suggested that he could find a soil microbe with the ability to produce an enzyme capable of dissolving the polysaccharide coating. Avery gave the young agricultural scientist a chance.

Thus, in 1927, René Dubos began a nearly fifty-year association with the Rockefeller Institute for Medical Research (later Rockefeller University). Only a two-year stint as George Fabyan Professor of Comparative Pathology and Tropical Medicine at Harvard Medical School, 1942 to 1944, interrupted his career-long affiliation with the Rockefeller Institute. As a medical researcher, Dubos made numerous contributions to bacteriology and medical science. In the Avery laboratory group, he extracted an enzyme from a soil microbe that proved effective against the polysaccharide coating of the lobar pneumonia bacillus. Although the advent of sulfa drugs precluded the use of the Dubos enzyme in the clinical treatment of pneumonia, the process he used to extract the enzyme proved beneficial in the late 1930s, when he returned to the soil to find a microbe with broader bactericidal properties. In 1939 he earned international recognition by developing gramicidin, the first clinically useful antibiotic. His success suggested the

clinical potential of soil microorganisms to researchers around the world. News of Dubos's advances spurred Oxford University's Howard Florey and Ernst Chain to resurrect Alexander Fleming's long-dormant research on penicillin. Dubos's work also inspired the effective development of streptomycin by his graduate school advisor, Selman Waksman. Collectively, these advances marked the beginning of the antibiotic era. Dubos's leading role in antibiotics research earned him the status of full member at the Rockefeller Institute, and, in 1941, election to the National Academy of Sciences.

Although his advances in antibiotics research represented his most celebrated contributions to medical science, they were by no means his only accomplishments. In the late 1940s Dubos gained recognition as an outstanding tuberculosis researcher. With the assistance of Bernard Davis, he developed an effective culture medium for tuberculosis bacilli. This new Tween-albumin medium permitted researchers to study the difference between virulent and nonvirulent bacilli and was credited with catalyzing a 'renaissance in tuberculosis research.' A strong advocate for vaccination against tuberculosis, Dubos also established guidelines for the standardization of BCG vaccines worldwide. Finally, in the 1950s Dubos collaborated with physicians in the Rockefeller Hospital on a study which revealed that prolonged bed rest did not expedite the recovery of tuberculosis patients receiving antibiotic therapy. This discovery had profound implications for sanatoriums, the traditional sites for tuberculosis treatment.

Despite his pathbreaking contributions to the modern pharmacopoeia, Dubos is more often remembered for his provocative ideas on human health. No one contributed more to the hubris of medical science at mid-century than Dubos with his breakthroughs in antibiotics research, but shortly after unveiling gramicidin, he publicized his concerns about the adequacy of antibiotic therapy for handling infectious disease. As early as 1942 he warned that the unmitigated enthusiasm for antibiotic wonder drugs should be tempered by a concern that overprescription of the drugs could lead to the development of more virulent, resistant bacterial strains. He argued that scientists gained an incomplete understanding of infectious disease when they focused solely on infectious agents. His studies of tuberculosis and the loss of his first wife to the disease taught him that, particularly in the case of latent infection, the host's ability to resist a disease is at least as important as the presence of an infectious agent. Pathologic processes, in his opinion, depended upon the total environment of the host, and deserved the serious attention of scientists. This challenge to the specific etiology of disease contributed significantly to the formulation of current conceptions which now include social factors, mental and physical disturbances, and environmental conditions in the understanding and management of disease.

Dubos's reconceptualization of disease, environment, and human health reached a broad audience of medical researchers, social scientists, politicians, and laypeople. He developed his ideas through over twenty books, countless articles in scholarly and popular journals, and an ever-increasing number of public addresses between the 1940s and the late 1970s. His most influential writings on human health include *The White Plague: Tuberculosis, Man, and Society* (1952), *Mirage of Health: Utopias, Progress, and Biological Change* (1987), and his Pulitzer-prize-winning text, *So Human an Animal: How We are Shaped by Surroundings and Events* (1998). In *The White Plague*, a book Dubos co-wrote with his second wife, Jean Porter Dubos, they mined historical accounts of tuberculosis outbreaks to demonstrate that the incidence of tuberculosis increased during times of social strife and decreased during less tumultuous eras. By linking it to poverty, they argued that tuberculosis was as much a social as well as a microbiological disease. In *Mirage of Health*, Dubos again challenged his readers to recognize disease as the indirect outcome of a constellation of circumstances rather than the direct result of a virulent microorganism.

Microbial disease, when it occurred, was due to an imbalance in the host's equilibrium caused by any of a number of factors in the external or internal environment – be it weather conditions, availability of food, working habits, emotional status, or emotional stress. Therefore, he argued, by ameliorating social and environmental conditions, social reformers had been more effective than scientists in reducing mankind's susceptibility to disease. Disease, according to Dubos, could not be eradicated simply by medical treatment. Social conditions must also be managed. His message enjoyed broad appeal among social scientists, many of whom, like Dubos, refocused their scholarly inquiries toward research that revealed how changes in an organism's social environment affected its health. Scientists also utilized Dubos's biopsychosocial perspective on health to construct a theoretical justification for the study of psychosomatic medicine.

By the 1970s, Dubos had become one of the USA's most visible scientists. His message appealed to a large number of Americans interested in the increasingly apparent connection between the environment and human health. Although organizations invited Dubos to speak on the environmental aspects of health and disease as early as the 1950s, his influence among environmentalists grew substantially after the publication of his Pulitzer-prize-winning book, *So Human an Animal*, in 1998. The book appeared when the USA was in the midst of the largest grassroots environmental movement in its history. Humans, like soil microbes, argued Dubos, adapt to their changing environments. Therefore, the quality of the environment in which a human develops holds great significance in the determination of human health and well-being. Although some environmentalists took issue with Dubos' notion that humans could improve on nature, many embraced him as an elder statesman of their movement. They adopted several of his maxims, including 'Think globally, but act locally' and 'Trend is not destiny,' as rallying cries for their cause. Dubos remained active in environmental activities years after his 1971 retirement from Rockefeller University. He co-wrote *Only One Earth* with economist and political scientist, Barbara Ward. This document provided scientific and social guidelines for the First UN Conference on the Human Environment in Stockholm in 1972. In 1977, Dubos lent his name to the New York-based René Dubos Center for Human Environments, an organization charged with the planning of international forums to promote beneficial human interventions into nature.

Dubos traveled an uncommon path from his early days as a French agricultural engineer to his respected position within the Rockefeller University and twentieth-century biomedical research. Although recognized and applauded as part of the scientific establishment by the 1940s, Dubos never hesitated to challenge the methodologies of his colleagues. Because he

believed that all living organisms must be understood in the context of their respective environments, he advocated less reductionistic laboratory research, studies that traversed interdisciplinary boundaries, and an ecological understanding of disease. He followed his inner logic outside the confines of scientific safety, where he found diverse and interested audiences willing to engage his provocative message. René Dubos died on his 81st birthday in New York City.

Due Process in Law

Abstract

This article assesses the history of the concept of due process in Anglo-American jurisprudence. While the actual phrase 'due process of law' first appeared in the Magna Carta, the concept of due process was transformed when the American colonists adopted it as a limiting principle not only on the use of executive power but also on the scope of the laws that could be passed. Due process protects substantive rights by requiring procedural regularity in the exercise of governmental power and insists that procedural regularity may not be altered by the normal operations of political power. In the twentieth century, due process law in the United States developed in three central phases – substantive, procedural, and functional due process – and these trends continue into the twenty-first century.

The concept of due process emerges from the central paradox in the creation of state authority. Following Thomas Hobbes (1994), the governmental state may be seen as an evolutionary response to the failings of the state of nature. In the war of all against all, no person has an incentive to industry, writes Hobbes in the *Leviathan*, because each lacks security in investment, planning, and the ability to exchange. Each faces the threat of bodily violence, invasion of the home, and seizure of property. The response, per Hobbes, is the creation of the state, a body that can impose order, lift mankind from the pitiable war of all against all, and secure collective benefits. The paradox emerges in that the creation of the state also produces a magnified form of the threat that was ever present in the state of nature. The state represents the largest entity capable of inflicting bodily violence, invading the home, and seizing property. Indeed, all states reserve to themselves the right to do just that to their citizens, and most include the right even to punish by death. What then differentiates the modern state that claims political legitimacy from the state of nature? The answer must begin with an abiding respect for procedural fairness in the imposition of punishment and the regulation of the conduct of the citizens' lives Thomas Hobbes (1994).

This conception of procedural fairness is at the heart of the concept of the rule of law, and of its more technically exigent offshoot, the guarantee of due process. The typical formulation of due process, as that concept has developed in Anglo-American jurisprudence, is derived from the Magna Carta, issued by King John in 1215 in the face of rebellious barons seeking restraint upon the exercise of royal prerogatives:

> No free man shall be seized or imprisoned, or stripped of his rights or possessings, or outlawed or exiled, or deprived of his standing in any other way, nor will we proceed with force against him, or send others to do so, except by the lawful judgment of his equals or by the law of the land.

The crux of the original formulation was to limit the power of the royal sovereign by granting legal protection to the life, liberty, and property of English freemen. The significance of the Magna Carta's guarantees emerges from the form of the limitation on sovereign authority. The document does not attempt to deny the sovereign the capacity to imprison, outlaw, or banish the rights-holding citizenry, or to have restraints imposed on the enjoyment of property or other rights held by citizens. Rather it imposes a condition of procedural regularity in the exercise of the sovereign's power, including central, orderly trial processes and formal proclamation of the applicable legal standards. This notion of procedural regularity is captured in the actual phrase, 'due process of law', which first appeared when the Magna Carta was issued in an English version in 1354 by King Edward III. Its modern vitality draws from the efforts of Sir Edward Coke in the seventeenth century to revive the Magna Carta as a check on the power of the Stuart monarchs.

Not surprisingly given these origins, due process emerged from medieval Britain primarily as a restraint on the executive power of the sovereign, specifically of the Crown. The concept of due process was transformed when the American colonists adapted the Magna Carta as a limiting principle not only on the use of executive power but also on the scope of the laws that could be passed. For colonists lacking the rights of participation in the creation of laws, the insult of arbitrary state power occurred whether power was exercised legislatively or by the sovereign. As recast by the colonists, due process became a limitation that extended beyond the power of the crown, to encompass as well local assemblies and, by the time of the revolution, Parliament. Thus, even as England adopted a system of increasing parliamentary sovereignty, the concept of due process as a constraint on the exercise of governmental power retained its vitality in the colonies. As a result, the newly independent Americans established a more limited government, reflected by the Bill of Rights (including a due process clause), as an explicit limitation on the use of state power, including the legislative branch. As articulated by James Madison, "The legislature, no less than the executive, is under limitations of power," and hence the rights of the people were to be secured 'against legislative as well as executive ambition' (Madison, 1896). The source of the limitation was a constitutional command that stood apart and above the normal operations of state authority.

The American focus on legislative power also highlights the importance of due process as a restraint not just on the penal powers of the state but on its civil regulatory powers as well.

 http://dx.doi.org/10.1016/B978-0-08-097086-8.86025-0

Due process emerges from this historical origin with two central features. First, it protects substantive rights independently secured by positive law by requiring procedural regularity in the exercise of all governmental power. Second, the requirement of procedural regularity may not be altered by the normal operations of political power. As reflected in the American constitutional experience, the guarantees of due process are not directly accountable to the political dictates of either the executive branch of government (the closest in form to the sovereign crown) or the legislative will of the majority. As a constitutional guarantee, the requirements of due process may not be altered though the customary political processes of legislation. It is these two features of procedural regularity and independence from direct political accountability that define due process as it has emerged most clearly in American constitutional law, which long ago held due process to be a protection of 'those fundamental principles of liberty and justice which lie at the base of all our civil and political institutions' (*Hurtado v. California*, 110 US 516, 535, 1884). Because the development is most clear in American constitutional law, that will serve as the template for further elaboration.

There are five basic elements of due process that may be adduced from American case development, particularly after the post-Civil War amendments to the Constitution extended the command to the conduct of the states toward their citizens. The two given the greatest significance are that, "Parties whose rights are to be affected are entitled to be heard; and in order that they may enjoy that right they must first be notified" (*Baldwin v. Hale*, 68 US (1 Wall.) 233, 1863). The opportunity to be heard and its "instrumental corollary, a promise of prior notice" (Tribe, 1988), according to the Supreme Court, 'seem to be universally prescribed in all systems of law established by civilized countries' (*Twining v. New Jersey*, 211 US 78, 110–111, 1908). The additional elements of due process are further corollaries necessary to make the right to a hearing meaningful: the right to an impartial arbiter, the right to be represented by counsel, and the right to timely resolution of claims.

The articulation of these elements of due process leaves unanswered a central question dating from the time of the Magna Carta: Are these due process rights intended as affirmative entitlements of the citizenry, as indispensable restraints on the state, or as instrumental checks against arbitrary, capricious, or simply misguided state conduct? Put another way, the constitutional enshrinement of a principle of due process can be seen as creating a distinct set of rights among the citizenry, or as a constraint on governmental processes. Measured against this template, it is possible to characterize the development of twentieth century due process law as passing through three central phases.

Substantive Due Process

The most forceful introduction of due process into the American constitutional canon came in the closing years of the nineteenth century with the emergence of the substantive due process doctrine. Federal courts gave independent substantive meaning to the Fourteenth Amendment's prohibition on states' restricting the enjoyment of life, liberty, or property without due process of law. Under this view, state incursions upon the affirmative rights of citizens to be secure in their life, liberty, and property were presumptively invalid and subject to exacting judicial scrutiny. The key to this period was an expansive set of presumed individual claims against state regulation. The domain of legitimate state activity was restricted to ensuring the public health, guarding against inherently hazardous activities, and protecting those who could not fend for themselves at law. This last group included (at the time) children, the mentally incompetent, and women. The most controversial feature of substantive due process came with the expansive definition of *liberty* to include a broad range of market freedoms that in turn prompted federal courts to strike down state regulatory measures by the dozens. Most famous no doubt was the Court's 1905 ruling in *Lochner v. New York* (198 US 45, 1905), a case that struck down a maximum hours regulation for the employment of bakers on the substantive due process grounds of 'liberty of contract'. The hallmark of this period was the use of a high threshold of procedural presumptions against the legitimacy of state regulatory initiatives. The period of substantive due process lasted until its repudiation by the Supreme Court in the New Deal period of the 1930s. Nonetheless, the reaction to the perceived hostility of the Court to progressive social legislation earned the *Lochner* period notoriety as a constitutional epithet and removed substantive due process from the constitutional lexicon, until its tentative re-emergence at the end of the twentieth century in difficult cases such as the constitutional review of assisted suicide (*Washington v. Glucksberg*, 521 US 702, 1997). Most recently, the Supreme Court has used the liberty guarantees of the due process clause to ground the privacy rights underlying reproductive freedoms and the constitutional protection of homosexual activity from criminal prosecution (*Lawrence v. Texas*, 539 US 558, 2003).

Procedural Due Process

The second great phase of due process activism came with the Warren Court of the 1960s. Unlike the *Lochner* period's focus on the expansion of substantive claims that triggered due process, the hallmark of the second phase was a focus on 'procedural due process', which was understood as an expansion of the process-based requirements for the state to act adverse to the interests of affected citizens. In a series of decisions involving legislatively conferred benefits, ranging from driver's licenses to welfare benefits, the Court interposed an elaborate series of processes required before such benefits could be withdrawn. The right to a hearing was repeatedly invoked in this period as an affirmative right of participation in governmental processes that inhered in the rights of citizens. The Court did not seek to expand the ambit of positive rights – entitlements were created by the normal processes of government – but instead used the due process clause to enforce heightened procedural hurdles before government could deny a benefit. Instead of the liberty to contract of the early twentieth century, the aggrieved due process claimant of the postwar period would claim a 'right to be heard' prior to adverse governmental action. Critics charged that the elevated procedural steps created a presumption against adverse governmental action almost as certain as that of the substantive

due process period. But more problematic, as evidenced in the ensuing case law, was how to reconcile near-categorical requirements of an inherent participatory right to process with a range of governmental conduct that required swift response to emergency situations. The case law struggled to find a mediating principle that would allow emergency responses, as with police searches, the impounding of goods in flight, the embargo on goods threatening public health or safety, and a range of comparable conduct whose successful implementation could not await notice and an adversarial hearing.

Due Process Functionalism

The tension in the heightened proceduralism of the Warren Court prompted a scaling back of inherent rights in favor of an instrumental approach to due process. Whereas both the substantive due process and procedural due process period had read the due process command to vest the citizenry with affirmative rights against the state, the functional period beginning in the mid-1970s saw in due process a check against improper or incorrect governmental decisions affecting life, liberty, or property. Thus, in the watershed case of *Mathews v. Eldridge* (424 US 319, 1976), the Supreme Court analyzed a challenge to the termination of social security disability benefits not in terms of whether due process protections attached, but rather in terms of how much process was due. By contrast to cases of the Warren Court period that assumed that process would have to be the full panoply of evidentiary protections, *Mathews v. Eldridge* held that the amount of process required prior to adverse governmental conduct would be determined by a balance of interests heavily weighted toward considerations of cost and likelihood of error:

> [D]ue process generally requires consideration of three distinct factors: first, the private interest that will be affected by the official action; second, the risk of an erroneous deprivation of such interest through the procedures used; and the probable value, if any, of additional or substituted procedural safeguards; and finally, the government's interest, including the function involved and the fiscal and administrative burdens that the additional or substitute procedural requirement would entail. (424 US at 334–335)

In the decades since *Mathews v. Eldridge*, this form of due process functionalism has come to command this area of American constitutional law. All the critical elements of due process – from the right to an evidentiary hearing to the right to counsel – are now subject to the balancing of magnitude of loss versus likelihood of error versus governmental interest in swift action. Some of the applications appear inevitable, as with the ability of police to immobilize illegally parked cars, even in the absence of notice and a prior hearing. Some are more problematic, as with the denial of the right to have counsel provided to an indigent prisoner facing civil proceeding for termination of parental rights.

The case of *Hamdi v. Rumsfeld* (542 US 507, 2004) offers a recent example in the freighted context of threats of terrorism. The petitioner, Yaser Esam Hamdi, was an American-born individual taken prisoner in Afghanistan during the American military action in 2002 and held as an 'enemy combatant' in a military prison on United States soil. The government's only evidence supporting Hamdi's classification as an enemy combatant would have been inadmissible as hearsay under most circumstances. However, Hamdi was not allowed to challenge the evidence and was not allowed to speak to a lawyer or contact his family, who themselves had to file a petition of *habeas corpus* on his behalf. Invoking *Mathews'* functional approach as the controlling law even in national security cases, the Court conceded that although a hearing was required, it need not, due to the needs of the government during wartime, necessarily include every procedural protection available in, say, a criminal trial. The exact details of the hearing were left to be developed subsequently, but the Court's message was clear: due process remains a vital protection even if its application must be flexible.

Nearly 800 years after the Magna Carta, this functional view of due process has firmly taken hold in the most developed of due process legal regimes.

Due Process in Other National Legal Systems

Broadly speaking, a large number of the fundamental rights accorded to individuals under the American conception of due process are also found in other nations' laws, with one critical caveat. The conception of due process, particularly in civil law systems, primarily addresses rights of criminal procedure – for example, the French Declaration of the Rights of Man, which explicitly grants the right to be free from arbitrary arrest and detention. Various international agreements, such as the Convention for the Protection of Human Rights and Fundamental Freedoms, contain similar language. Many national constitutions similarly guarantee the rights to notice, choice of counsel, a speedy trial, and appeal.

Even in the sphere of criminal procedure, there are significant differences between the American notion of due process and that found in other countries. Perhaps the most striking example is the absence in many legal regimes of the right to be presumed innocent that is considered so fundamental in the United States. Also absent in many countries is a notion that both sides in a criminal trial have equal opportunity to advocate their positions.

More revealing is a comparison of the American and German conceptions of due process. On one level, the two countries' approaches are similar. Both put a pre-eminent value on human liberty. Thus, Article 1(1) of the German constitution states that "the dignity of man shall be inviolable." This notion of human dignity is akin to the American concept of substantive due process. Both are tools that have been utilized by the respective courts to 'discover' hitherto unenumerated rights. In this sense, both countries have a conception of due process that is, to a certain extent, open ended. As a consequence, both must grapple with an abstract and amorphous concept, often with controversial results.

But perhaps the most fundamental difference lies in their highest courts' approaches to constitutional interpretation. While the German Constitutional Court has interpreted its constitutional mandate to develop a systematic approach to constitutional jurisprudence, the United States Supreme Court, by emphasizing procedural regularity, has exhibited a tendency to

act in a piecemeal fashion. The result is that, in some ways, the German view of due process appears even more comprehensive than that of the United States. Most importantly, Germany guarantees the protection of 'personality rights' and 'physical integrity', which are akin to the American procedural due process. But, unlike the United States Supreme Court, which has often worked to construe due process narrowly, the German Constitutional Court has consistently taken a broad view of due process, viewing as properly furthering the fundamental principle of human dignity – a far more sweeping command than recognized in the initial procedural focus of Anglo-American law.

Abstract

Durkheim's vision of sociology went beyond the scientific to the moral and political, incorporating a distinctive diagnosis of modern society's ills. His several sociological classics remain central through successive critiques and reinterpretations. His major contributions to methodology, to the analysis of types of solidarity and suicide, and his sociology of religion and knowledge are reviewed; also his continuing influence and current significance are assessed. He has profoundly shaped social scientists' understanding of industrialization, urbanization, social control, social disorganization (with the concept of 'anomie'), collective behavior, the ritual and symbolic aspects of punishment, his thoroughly social account of religion, and of the social shaping of cognition and classification.

Émile Durkheim's writings, though they cover a vast range of topics, reveal a single, focused, organizing vision of sociology's subject matter and objectives. These went beyond the purely scientific, and were also moral and political. He sought, through education, to contribute to the stability and legitimacy of the French Third Republic and, more widely, to find cures for modern society's ills. His writings include several classics that remain central to the discipline of sociology, through teaching and through successive reinterpretations in which advances continue to occur by confrontation with Durkheim's ideas. These ideas, developed in close collaboration with a school of remarkably talented younger colleagues grouped around the journal, *L'Année sociologique*, which flourished before World War I, had a considerable impact within France and later far beyond, within sociology and across several other disciplines.

Biography

Born on 15 April 1858 in Épinal in the Alsace-Lorraine region into a close-knit rabbinic family, he abandoned Judaism at an early age. He thereafter treated religion agnostically as a social phenomenon demanding sociological explanation (from the mid-1890s, it was increasingly central to his thought), yet maintained that in studying it one is blind without a certain religious sentiment. After his studies at the *École normale supérieure* in Paris, he taught philosophy in secondary schools. On a government grant he visited Germany, for whose scientific education there was widespread admiration in defeated France. His encounter with German social scientists strengthened his so-called 'social realism.' In 1887, he was appointed to teach social science and pedagogy at the University of Bordeaux, as part of a national drive for a new system of republican, secular education. In 1896, he was appointed as the first Professor of Social Science in France and in 1897, founded *L'Année sociologique*. While at Bordeaux, he published three major works: *The Division of Labor in Society* (Durkheim, 1893[1902]), *The Rules of Sociological Method* (Durkheim, 1895[1901]), and *Suicide* (Durkheim, 1897) and his Latin doctoral thesis on Montesquieu. He also lectured and published across a wide range of topics including education, the family, the incest taboo, crime and social health, the evolution of punishment, the state, professional ethics and civic morals, religion, Rousseau, the history of sociology, and the history of socialism – the last in response to his students' political concerns. Averse to the sharpening of class conflict and believing revolutions to be as impossible as miracles, he stressed the need for institutional reforms that would encourage cross-class solidarity around common principles of social justice. He favored an interventionist State offset by a plurality of local, civic, and especially occupational associations, believing that out of this conflict of social forces individual liberties are born (Durkheim, 1950). He remained close to the liberal socialism of Jean Jaurès, but in the late 1890s, the Dreyfus Affair induced him to break his principle that the social scientist should be, as such, kept away from everyday politics. An active Dreyfusard, he denounced those who defended the army and the Church as sacred national institutions and proclaimed that modern society could only be integrated around the religion of individualism, protecting the sacredness of the individual and individual rights, the 'sole link' still binding citizens to one another.

In 1902, he moved to Paris to teach education and sociology. He continued to lecture and write across a wide range, publishing a study of *Primitive Classification* with Marcel Mauss (Durkheim and Mauss, 1903) and his masterpiece *The Elementary Forms of the Religious Life* (Durkheim, 1912). He debated with philosophers, historians, and psychologists and exercised a magisterial influence on the institutional development of sociology and on educational thinking and practice in France. On all these fronts, his doctrines generated controversy and opposition, often fierce, to which he responded vigorously. Much of his energy went into the editing of *L'Année*, of which 12 volumes had appeared by 1913. These contained monographs and reviews of works in many disciplines and languages, systematically classified and mined for their theoretical and empirical usefulness to a progressing research program. An extraordinary collaborative achievement, they constitute the Durkheimians' ongoing debate with the sociologically relevant literature of their time, distinctive, among other things, in its comprehensive attention to the ethnographic record of the world's remoter peoples. All of this ended with the onset of the World War on whose battlefields several, including the most brilliant and promising of them, including Durkheim's son Andre, met their deaths. For a second time,

 http://dx.doi.org/10.1016/B978-0-08-097086-8.61027-9

Durkheim broke his principle of political noninvolvement, contributing to the war effort and writing patriotic pamphlets, but, unable to overcome his grief at his son's death, he died in Paris on 15 November 1917.

Major Contributions

The focus of Durkheim's sociological vision was his so-called 'social realism': the view that social phenomena, or as he called them *faits sociaux*, are *sui generis*, with their own characteristics: they are general among, external to, independent of, and constraining upon particular individuals and typically are recognizable by their obligatory force. They constitute a distinct level of reality and are not reducible to the meeting of individual intentions. Hence, his attacks on social contract theorizing and on other forms of methodological individualism that attempted just such a reduction, as practiced for instance by utilitarians, economists, psychologists, and the English sociologist Herbert Spencer. At different stages, he focused on *faits sociaux* of different kinds: on 'morphological' phenomena such as population volume and 'dynamic density' and spatial distribution, on types of law (see Cotterrell, 1999), on institutions and, increasingly, on what he came to call *représentations collectives* (Durkheim, 1924). By this he meant collective ideas and sentiments, which could, moreover, be evanescent, like crowd enthusiasms or fashions, or more 'crystallized' or institutionalized, like legal codes or most stable of all, the fundamental categories of thought. *Faits sociaux* were what we would now call emergent phenomena whose properties, resulting from the structured interactions of their constituents, could not be accounted for exhaustively in terms of individuals' presocial properties.

Durkheim advanced this view polemically, as a doctrine, above all in *The Rules*. It has been suggested that this is best understood in its context as the forging of a vocabulary suited to securing French citizens' allegiance to their Republic (Jones, 1999). What is certain is that Durkheim's social realist rhetoric generated unproductive controversies and, worse, led to misunderstandings that have, even until today, deflected attention from his explanatory practice, to which his methodological pronouncements are an inadequate guide. Thus, he claimed that only social causes can explain social effects and that every time a social fact is explained directly by a psychological fact one could be sure the explanation is false. In various places he uses language that personifies collectivities, making 'society' appear as a subject of experience, with a *conscience commune*, or as an agent with a unified will, requiring conformity, pursuing ends, and imposing ways of acting on its members.

But against such passages one can cite others that stress that society only exists in and through individuals, that neither can exist without the other, and that representations collectives are the product of individuals' activity and, indeed, of an immense cooperation extending across space and time. In fact, Durkheim's actual explanations are by no means confined to the macrolevel; he sometimes seeks to explain the micro by the macro, as in *Suicide*, and the generation of macrophenomena at the microlevel, as in the generation and regeneration of religious faith through collective effervescences and rituals in *The Elementary Forms*. In short, Durkheim's explanatory practice was interactionist, not holistic. Unfortunately, his polemical antimethodological individualism and hostility to psychological explanation precluded him from reflecting on the microunderpinnings of his macroexplanations and, in general, on micro–macro connections, so that these aspects of his explanations remain undertheorized. Yet this very inattention may have generated insights. By not seeing certain things, perhaps he focused more intensely on what he did see. *Faits sociaux*, he wrote in *The Rules*, should be treated 'as things' ('*comme des choses*'), independent of and external to observers as well as actors, and enabling one to decide between competing theories. This expresses his commitment to scientific method as he saw it, as against philosophical theorizing uncontrolled by empirical evidence (to philosophize, he once told a doctoral candidate, is to think what one wants) and as against the Positivism of Comte, committed to the identification of a small set of transhistorical laws, rather than the systematic study of specific causal mechanisms (he rejected the label 'positivist,' preferring that of 'rationalist'). Social scientic method required the abandonment of pretheoretical preconceptions, the systematic testing of theories by evidence, quantitative where appropriate (as amply illustrated in *Suicide*), the careful selection of indicators, the rejection of teleological and functional explanations (though not the identification of social functions), the use of comparison (sociology's substitute for experiment), and the construction of social typologies. He conceived of types of society within a broadly evolutionary framework, proceeding from the least to the most advanced societies (and citing recent and contemporary tribal societies and those of Antiquity as instances of the former). He further thought that one could distinguish between 'normal' and 'pathological' developments within each type, at each stage of its development. This enabled him, he thought, to diagnose certain aspects of modern industrial societies, notably the prevalence of *anomie*, as pathological. The problem here was that his notion of normality was ambiguous between a statistical definition and one that embodied an implicit theory of social and psychological health or equilibrium relative to a given society's 'conditions of existence.' (How could a pathological phenomenon be both prevalent and abnormal?) Such diagnosis and the elaboration of feasible institutional remedies were, he thought, the chief ways in which the sociologist could contribute to social progress.

The *Division of Labor* contains (1) the positing of two ideal types of society, which Durkheim took to characterize less and more advanced societies respectively (but which can evidently coexist); (2) an analysis of the mechanisms claimed to explain the transition from the former to the latter; and (3) a diagnosis of the latter's pathological forms. Mechanical solidarity, held to typify preindustrial societies, based on resemblances, exhibits identical and juxtaposed elements, segmentally structured and with weak social bonds, low population volume and moral density, undifferentiated social organization, repressive or penal law, and collective beliefs and sentiments (which at that stage he called the *conscience collective*) that strongly tie the individual to the society as a whole, while organic solidarity, typical of industrialized societies (in their 'normal' state of functioning), based on the division of labor, the fusion of markets, and the growth of cities, exhibits interdependence and

strong social bonds, high volume and density, an increasing differentiation of social functions, restitutive or cooperative law, the gradual withering away of the *conscience collective*, and the emancipation of the individual, allowing space for individual initiative and reflection. The transition from mechanical to organic solidarity, which constituted the 'progress of the division of labor and civilization,' occurs, Durkheim maintained, 'mechanically' as a consequence of growth in the social mass and its social or dynamic density, through expanding markets, a 'struggle for existence,' a resultant development of new occupations and corresponding consumer demand. Durkheim intuitively assumed an equilibrium outcome of increasing division of labor but did not specify the parameters that would generate that outcome. The division of labor exhibits perverse effects and thus abnormal forms where the conditions for the social equilibrium of organic solidarity are not satisfied. *Anomie* – the lack of appropriate rules – is evident in industrial and commercial crises, veering between prosperity and depression, resulting from ignorance and uncertainty of producers concerning demand, in the antagonism between capital and labor, and also in increasingly fragmented scientific specialization, and results in general from a too rapid industrialization in which the appropriate rules have not had time to stabilize relations between social functions and roles. The 'forced division of labor' exists where inequality is seen as illegitimate, as when unequal chances of mobility violate the meritocratic principle. And a third abnormal form, which Besnard calls 'bureaucratic' (Besnard, 1987), is found where excessive specialization is combined with weak productivity and poor mutual adaptation of functions.

Durkheim considerably deepened his notion of *anomie* and his diagnosis of capitalism's ills in *Suicide*. *Anomie* is one of the two major modern social causes of suicide: a condition of rulelessness in which individuals lose their moorings; their expectations exceed the possibilities of satisfying them, potentially insatiable, desires are no longer regulated within a stable and legitimate normative framework of economic rewards or status ranking or conjugal sexual relations. The other major modern social condition causing suicide is egoism: a breakdown of integration, a lack of attachment of individuals to common values, to socially approved relationships, activities, and purposes, isolating and privatizing their lives. (Excessive regulation, or fatalism, and excessive integration, or altruism, are less prevalent, Durkheim thought, in modern societies.) Suicide is the extreme response of the small, randomly distributed but statistically stable minority of suicide-prone individuals whose social situations expose them to the social causes in question. He expounded this theory by accounting for differential suicide rates (e.g., higher among Protestants than Catholics, lower among married men, higher during economic crises, lower during wars) by characterizing suicide's social causes as 'suicidogenic currents,' thereby suggesting a macro–macro explanation that evaded the microlevel, in line with his antiindividualist methodological stance. In reality, his theory of suicide is a macro–micro theory of the social conditions for individual psychological equilibrium, or health (*anomie* being the 'malady of infinite aspiration') that stance deflected him from elaborating. *Suicide* has been widely seen as remarkable for its sophisticated use of statistics (albeit questionable in abstracting from suicide's social meanings to which, likewise, Durkheim paid no attention), including the use of multivariate analysis to exclude alternative explanations. But above all, the work exhibits its author's typical boldness in extending sociological explanation to what might seem least amenable to it: the most private and individual of acts. The same boldness is evident in *The Elementary Forms*, whose introduction and conclusion advance a theory of the fundamental categories of thought, while the rest of the work advances a theory of the origins, meaning and functions of religious beliefs and practices, magic, and the relation of both to science. All this he developed with reference to ethnographic evidence of totemism (assumed to be the most primitive form of religion and its evolutionary origin, or at least its earliest known form) as found in 'simpler,' tribal societies in Australia and America. He made the questionable assumption that the essential elements of religious thought and life should be found, at least in germ, in the most primitive religions, regarding the study of a 'very simple' religion as particularly instructive, since the relations between its constituent elements are 'more apparent' there.

Observing that such categories as space, time, number, causality, the person, etc., impose themselves on us inescapably as the framework of our understanding, Durkheim rejected as nonexplanatory Kant's account of them as given a priori, arguing that they express the most general relations existing between things, which are revealed to us through social action and mutual communication; their necessity has a social basis. Moreover, they are fundamental to commonsense and to science (natural and social) and across cultures. Religion he defined by its universal dichotomizing of the world into the sacred and the profane, uniting believers around the sacred, to which they accord a special, awed respect. Starting from the assumption that religious beliefs cannot be illusory (for otherwise they would not persist), he asked to what reality they correspond, answering that, once decoded, they express our understanding of our society and our obscure and intimate relations with it. They require decoding since, until social science, these cannot be apprehended directly: religion is, in this respect, a sort of mythological protosociology. (Thus, the idea of the soul is the way religion represents the duality of human nature, part corporeal, part social.)

This exclusively society-oriented interpretation of religious symbolism has been much criticized (it was Durkheim, not the savage, Evans-Pritchard suggested, who made society into a God). A further contentious issue is whether or not accepting it challenges religious belief (Durkheim claimed it did not). In the domain of knowledge, science replaces religion but religion continues to symbolize and dramatize social relations, strengthening and reanimating social bonds and believers themselves through the collective enactment of rituals. This aspect of religion survives and would, he speculated, remain basic to the political cohesion of modern, secular societies as civil religion. Religious beliefs themselves originate in such collective effervescences and are renewed by their reenactment.

Cognitively, religions are, he held, cosmologies, offering a 'first explanation of the world,' seeking realities behind appearances, teaching people to unite what the senses separate, and thus prefiguring science. Religion and science are alike in that they both seek to render the (natural and social) world intelligible, but only the latter disposes off methods that

subject its observations to systematic control. Likewise, magic, which occurs within profane or everyday life, draws on prevailing religious beliefs and seeks to predict and manipulate the world, but without benefit of scientific tests, statistics, or experiments, adducing (as scientists also do) auxiliary hypotheses to account for its failures. So for Durkheim, human thinking is unitary, not, as Lucien Lévy-Bruhl thought, divided into two stages – prelogical primitive thinking and logical, science-based modern thinking.

Influence, Impact, and Current Significance

His collaborators applied and developed Durkheim's ideas in many directions, from economics to Chinese thought (in the work of Marcel Granet) to primitive and ancient law (see Besnard, 1983). They also had a considerable contemporary impact on neighboring disciplines in France, for instance, on historians, initially through Henri Berr and his *Revue de synthése historique* and later through Lucien Febvre, Marc Bloch, and the *Annales* school, on human geography, beginning with Paul Vidal de la Blache, on jurists, notably Léon Duguit, and on the study of comparative mythology in the work of Georges Dumézil. The surviving Durkheimians continued into the 1930s but their research program gradually lost its dynamism and, as Raymond Aron observed, it came to seem increasingly irrelevant to the times. Among those who have made a significant impact on subsequent work, one can single out Robert Hertz's studies of death and of right and left (Hertz, 1907, 1909), Maurice Halbwachs's work on collective memory (Halbwachs, 1925) and, above all, Marcel Mauss, Durkheim's nephew, pupil and collaborator, author of several major works on Durkheimian themes, including magic and sacrifice (coauthored with Henri Hubert), seasonal variations among the Eskimos (with Henri Beuchat), the techniques of the body and the category of the person (Mauss, 1950), who succeeded in breaking down Durkheim's conceptual dichotomies and methodological rigidities vis-à-vis other disciplines, in the interest of studying the *fait social total*, as in his classic and influential study of *The Gift* (Mauss, 1925). In several ways, Mauss rendered Durkheimian sociology more subtle, complex, and forward looking. Through Mauss, it influenced French structuralism via his impact on Claude Lévi-Strauss (see his introduction to Mauss, 1950) and also on Louis Dumont, author of the major work on the Indian caste system, *Homo Hierarchicus* and of parallel studies of Western individualism. Its influence is also evident in the *Revue de MAUSS* (*Mouvement antiutilitariste en sciences socials*), which, since 1993 has published antiutilitarian articles on various aspects of social life. Among French sociologists, Georges Friedmann, Pierre Bourdieu, and Raymond Boudon (see Boudon, 1999) have incorporated Durkheimian ideas, albeit far from uncritically, the latter insisting upon a convincing interactionist reading of Durkheim. This has, in turn, been developed by Mohamed Cherkaoui (Cherkaoui, 1998) who has, moreover, resurrected for close attention Durkheim's sociology of education, in particular his remarkable study of the evolution of French educational thought and institutions, and their interaction, since the early Church (Durkheim, 1938), which explores various themes less than evident in his better known works: class power and conflict and the struggle for cultural domination, the role of intellectuals, and the sociology of educational knowledge focusing on dominant epistemologies and disciplinary hierarchies. Another important work is the definitive study of the concept of anomie and its career within sociology (Besnard, 1987). Besnard also inaugurated the valuable *Études durkheimiennes* in Paris in 1977 as a forum for scholarship on Durkheim and the Durkheimians. It moved to Urbana, Illinois under the editorship of Robert Alun Jones in 1989 and to Oxford in 1995, published by the British Centre for Durkheimian Studies under the inspiration of William Pickering, along with a continuing series of important Occasional Papers edited by Willie Watts Miller.

The Durkheim school's impact on British social anthropology has been immense, initially through Radcliffe-Brown but chiefly through his successor E.E. Evans-Pritchard, whom it helped liberate from his predecessor's structural-functionalism. Despite serious reservations, he identified himself with the work of the Durkheimians, praising it as an indispensable theoretical capital, embodying rigorous methods of scholarship (see his introduction to Hertz, 1907). In the early 1950s, he launched an extensive series of English translations of works by Durkheim and his collaborators, and himself drew on Durkheimian ideas, especially in his work on the Nuer. The impact of Durkheimian ideas is also evident in the work of other Oxford anthropologists, particularly that of Rodney Needham and Nick Allen on symbolic classification, but also in the various writings of Mary Douglas on pollution and symbolic boundaries, and in the work of Robin Horton on African religions.

Durkheim's reception into American sociology began early, influencing, among others, Elton Mayo and W. Lloyd Warner, but it was Talcott Parsons's extended treatment of his work in his *Structure of Social Action* that marked his canonization as a 'grand theorist,' treated there as a pre-Parsonian protostructural functionalist, with a distinctive solution to the 'problem of order' through the internalization and institutionalization of consensual, society-wide values.

Durkheim's famous account of social facts as *sui generis* in *The Rules of Sociological Method* was for long dismissed as unacceptable but has achieved a new lease of life with increasing acceptance of the idea of 'emergence,' according to which patterns and outcomes occurring at a higher level may be neither explicable nor predictable at a lower level. Just as theories, concepts, laws, and terminology at the psychological level may be irreducible to the neurobiological, while mental events and properties have real effects there, the same may be true of the social level vis-à-vis the level of interacting individuals, without any ontological implication of the existence of a 'group mind' or the like. Durkheim himself argued this and can thus be seen as a theorist of emergence *avant la lettre*.

Substantively, the impact of his ideas was pervasive, influencing innumerable accounts of industrialization, urbanization, social control, social disorganization, and collective behavior. These were, directly or indirectly, extrapolated from Durkheim's picture of advancing social differentiation leading through rapid social change to the breakdown of social ties. According to such accounts, rapid industrialization generates disharmony between life experiences and the normative framework, which regulates them, leading to virtually unlimited possibilities for group conflict and thus to a variety of social movements: peaceful

agitation, political violence, millenarianism, nationalism, revolution, underground subversion, etc., that in turn attract those suffering most severely under the displacements created by structural change. Examples of this approach are found in the work of Samuel Huntington, Chalmers Johnson, Ted Gurr, and Neil Smelser. Such accounts were criticized by Tilly (1981) for relying on three basic 'Durkheimian' arguments that are held to have been refuted by the historical evidence: (1) that conflict varies directly with the prevalence of differentiation within organization and the scale of groups; (2) that social disorder correlates with accelerated urbanization or industrial growth; and (3) that the various forms of 'disorder,' such as crime, suicide, conflict, and protest, vary together, in the same settings and circumstances. In short, Tilly rejects the 'Durkheimian line' on conflict, protest, and collective action, which he explains instead in terms of group solidarities, common interests, and mobilization. But, first, the 'line' is extrapolated from, not argued by, Durkheim, who never sought to explain so much by so little; it is his American successors, not Durkheim, who posited the strains resulting from rapid industrialization as the catch-all source of so many 'disorders,' which he never treated as equivalent and associated. Second, his ideas about the processes creating and reanimating collective solidarity are surely not irrelevant to the explanation of collective action. And third, his focus on the consequences of rapid economic and social change outstripping the norms that could regulate it has an inescapable relevance for the diagnosis of the distinctive ills of the most advanced forms of contemporary capitalism, in particular the corrosive effects of technical change on social relations and individual lives.

The concept of *anomie* has had an impact in other fields. Robert Merton imported it in his influential paper on *Social Structure* and *Anomie* (Merton, 1949) but in the process mis- or reinterpreted Durkheim's notion as a maladaptation of means to ends, rather than a sociopsychological condition of deregulation (so that the problem, on Durkheim's account, should be seen as lying in the success ethic itself, not in the socially structured inability of some to realize its promises). But this idea, together with the other causes of suicide, and indeed the structure, content and mode of its attempted explanation, have exercised a continuing and productive stimulus within the sociology of deviance and criminology, as often through attempts to develop or revise Durkheim's contribution as through more or less radical refutations of his whole approach.

Within the sociology of law, Durkheim has had a major, recently revived and continuingly fertile impact. Here the central influential idea, foundational to the contemporary sociology of punishment, has been his account of crime and punishment: crime is deviant conduct that violates prevailing norms and offends the consciences of the upright, provoking them to passionately felt punitive reactions that are authoritatively enforced by law. Punishment thus serves not to control crime but to sustain and enhance solidarity through ritual ceremonies and symbolic effects. More specific, and most striking, has been his insight into the paradox that punishment presupposes and does not create attachment; its function of moral condemnation undermines its preventive or retributive effectiveness, insofar as offenders' attachment to the moral community is weak or minimal. This insight can be seen developed in the two major present-day sociologists of punishment, despite their very different approaches, namely David Garland and Loic Wacquant, both of whom readily acknowledge indebtedness to Durkheim.

It is, however, his later 'religious sociology' that has had most impact within sociology since the 1990s, applying its concepts, insights, and hypotheses to historical and modern societies. Durkheim and the Durkheimians never did this, and indeed a surprised Mauss could write in the late 1930s, contemplating Nazism and Fascism, of the tragic 'verification' of their theory in the spectacle of large modern societies "hypnotized like Australians [aborigines] are by their dances" (Ranulf, 1939; cited in Lukes, 1972). From the 1960s through the 1980s, practitioners of historical sociology were largely focused on the rise and development of capitalism and were class-oriented and state-centered in approach: Marx, Weber, and Tocqueville were the presiding ancestors. Since then a growing interest in cultural analysis has been evident, with an associated interest in Durkheimian ideas. Initially, this development had a Parsonian, consensual emphasis. Edward Shils argued that secular, differentiated societies have sacred 'centers' that explain the allocation of status (Shils, 1975), Clifford Geertz interpreted cultural systems in a way that linked sacredness, ritual and the mobilization of solidarity (Geertz, 1973), and Robert Bellah published and stimulated studies of civil religion under modern conditions (Bellah and Hammond, 1980). More recently, there has been a growing interest in symbolism and ritual and their relation to the institutionalization of power and social control but without the assumption of social consensus. In Jeffrey Alexander's words, a 'late Durkheimian framework' is applied to 'analyze phenomena, which are disruptive, contingent, and related to social change,' while Randall Collins, exponent of conflict sociology, has sought to combine Durkheim with Erving Goffman, in exploring how 'focused and emotionally arousing interaction produces group solidarity' (Alexander, 1988). Studies along such 'late Durkheimian' lines have included French Revolutionary festivals, ritual and symbolism under Fascism, nationalist movements, mass strikes, and media events. Among contemporary social and cultural anthropologists, Joel Robbins, who draws on Collins's theory of ritual chains, and Maurice Bloch, who draws on cognitive science, have both attempted to preserve Durkheimian insights by means of arguments that differ from those he himself employed: Bloch distinguishes 'the transcendental social' of imagination from 'the transactional social' of everyday interaction, while Robbins focuses on the heightened emotional energy generated by ritual collective effervescences.

These are the main lines of Durkheim's impact upon twentieth-century social science. I have not discussed his impact beyond the social sciences (for example, on and through such partly literary figures as Roger Caillois, Michel Leiris, and George Bataille, members of the so-called *Collège de Sociologie* in the late 1930s), or countless unacknowledged influences. More specific and acknowledged social scientific influences could also be cited, for instance, upon the work of Basil Bernstein on sociolinguistic and educational 'codes,' drawing on Durkheim's ideal-typical polarities, and upon the so-called 'strong program' in the sociology of science, originating in the University of Edinburgh, focusing, in a relativizing vein, on the 'social' origins of 'natural' classifications (see Bloor, 1976). Here, as ever, Durkheim's ideas are interpreted in

accordance with locally generated concerns. The story of their reception, sketched here, confirms both their continuing attraction and their continuing power to generate alternative and invariably controversial readings.

Abstract

Strictly speaking, the Durkheimians are the disciples of Durkheim. But, who were these disciples? Mainly, his collaborators on the journal *L'Année sociologique*. The first part of this article is a sociological analysis of the characteristics of this group of 50 collaborators: their disciplinary backgrounds, networks, generations, and participation to the journal. The second part is an analysis of the 'destiny' of this French School of Sociology since Durkheim's death until today with the presentation of two new trends: a renewal of the Durkheimian studies and the development of a Neo-Durkheimian perspective in sociology.

The substantive 'Durkheimian' is related to Émile Durkheim (1858–1917), the founder of sociology in France. Strictly speaking, the Durkheimians are the disciples of Durkheim. But, who were these disciples? Mainly, his collaborators on the journal *L'Année sociologique*, but they were not the only ones. Some Durkheimians belonged to the network of this group of collaborators or had intellectual affinities with Durkheim: Lucien Levy-Bruhl was a friend and colleague of Durkheim at the Sorbonne and close to Durkheim's disciples who were members of the Socialist Party, but he never collaborated with *L'Année*; he became a Durkheimian while keeping his intellectual independence for almost his entire life, defending the thesis of a 'prelogical mind' against Durkheim himself. Other scholars published articles in the journal but were excluded – such as Henri Muffand, a colleague of Bouglé at the Lycée, who was too close to anthroposociology – or maintained a critical distance from Durkheim: Gaston (born in 1860), author of a book entitled *Essais sur l'origine du droit* (1892), was a member of the first group of collaborators, responsible for the section on criminology. Thus, it was possible to collaborate with *L'Année sociologique* without being a Durkheimian, and vice versa.

The first volume of *L'Année sociologique*, founding the journal's founding in 1896, was published 2 years later. This volume was the first in a series of 13 to be published under the direction of Émile Durkheim. A second series of just two volumes (1925 and 1927) was published after the First World War under the direction of Marcel Mauss (1872–1950).

Philippe Besnard has published an excellent analysis of the first series of *L'Année*, identifying the first group of founders and the internal networks of all collaborators (Besnard, 1979). The founder of the journal was Émile Durkheim, but it would seem that Celestin Bouglé, a young philosopher, was the one to have the idea and suggested to Durkheim that he create the journal. Durkheim debated the general orientation of the journal with Bouglé and his friend Paul Lapie: the issue was the distinction between sociology and psychology. Durkheim agreed to define sociology as a form of psychology, but a specific one, i.e., collective psychology.

Émile Durkheim also succeeded in involving his nephew, Marcel Mauss, then a young *agrégé de philosophie* and a student in history of religion at the École Pratique des Hautes Études: "[…] Il n'est pas nécessaire d'être beaucoup: le fait que nous ne soyons que deux nous singularise déjà" [There is no need to be many; the fact that there are just two of us already sets us apart] (Durkheim, 1897: p. 81). Mauss' job was to convince some of his friends, also *agrégés*, to take part in this adventure and become sociologists: Henri Hubert, Paul Fauconnet, Emmanuel Lévy, Albert Milhaud. The 'top brass' of the team included Bouglé, Fauconnet, Hubert, Mauss, and Simiand, and they were among the most active collaborators.

The new journal had two parts: the first part consisting of two or three essays (the 'Mémoires' in the first volume were a translation of G. Simmel's paper, *Comment les formes sociales se maintiennent*, and an original paper by Durkheim, *Prohibition de l'inceste et ses origines*) and the second with book reviews. It was the journal's 'mission' to describe the 'current state of literature' in the social sciences, according to Durkheim, who introduced a division of labor between his collaborators, giving each of them responsibility for sections of reviews. In the first issue of *L'Année*, these were: General Sociology (C. Bouglé), Religious Sociology (M. Mauss and H. Hubert), Moral Sociology & Sociology of Law (P. Lapie, E. Lévy, E. Durkheim, M. Mauss), Criminal Sociology (G. Richard), Sociology of Economics (F. Simiand), and miscellaneous (H. Muffang, E. Durkheim, P. Fauconnet, and D. Parodi). The two largest sections were Religious Sociology, and Moral Sociology & Sociology of Law.

The list of the collaborators in the first series, ranked by how important their collaboration was (i.e., the number of reviews they wrote) is E. Durkheim, M. Mauss, H. Hubert, F. Simiand, G. Richard, H. Bourgin, P. Fauconnet, C. Bouglé, M. Halbwachs, P. Lapie, P. Huvelin, D. Parodi, G. Bourgin, A. Meillet, R. Hertz, G. Davy, E. Lévy, A. Aubin, P. Hourticq, J. Ray, H. Muffang, A. Bianconi, Ph. de Felice, I. Levy, Ls. Gernet, A. Milhaud, Ed. Laskine, J. Marx, L. Reynier, H. Beuchat, M. David, Ré Challié, G. Gelly, Poirot, J.T. Stickney, A. Vacher, E. Doutté, H. Jeanmaire, A. Demangeon, Foucault, F. Sigel, P. Roussel, Ch. Fossey, P. Lafitte, Ch. Lalo, E. Claude Maître, and A. Moret (Besnard, 1979).

These almost 50 collaborators published more than 2000 book reviews. Some of them contributed to all the volumes (Durkheim, Mauss, Hubert, Simiand), others to several volumes, and still others to just one. They came from different disciplines (philosophy, philology, archeology and history, geography, linguistics, etc.). Durkheim held a central position, but there were different networks: Bouglé, Lapie, and Parodi; Simiand, Halbwachs, and the Bourgin brothers; Mauss, Hubert, and their students. We can identify three generations: (1) the elders (born

 http://dx.doi.org/10.1016/B978-0-08-097086-8.61191-1

before 1860), with Durkheim, Richard, and colleagues (Meillet, Moret); (2) the generation born between 1870 and 1880 with the students of Durkheim at Bordeaux (A. Aubin, M. Foucault, R. Hourticq, Ch. Lalo) and his nephew Marcel Mauss and his friends (Hubert, Fauconnet, Simiand); and (3) the generation of younger scholars, with students of Mauss and Hubert at École Pratique des Hautes Études (H. Beuchat, M. David, G. Davy, L. Gernet, R. Hertz, H. Jeanmaire, Ph. De Felice, J.P. Lafitte, J. Marx, J.P. Reynier, P. Roussel).

The team of *L'Année* was a real research laboratory: 18 essays ('Mémoires') were written by the collaborators. There were not only collaborations between them (Durkheim and Mauss, Mauss and Hubert, etc.) but also intense debates. This was a challenging, but ultimately successful, enterprise that gave visibility to the 'French school of sociology,' which was 'Durkheimian sociology.'

The institutionalization of this school was confirmed when its members gained positions in the educational system: in *lycées*, universities (Bordeaux, Toulouse, Paris), and other schools and institutions (École Pratique des Hautes Études, Conservatoire National des Arts et Métiers). Some of them also published papers and books discussing and defending the Durkheimian perspective in sociology, from *Sociologie: l'objet et la méthode* by Mauss and Fauconnet (1900) to *La sociologie de Durkheim* (1911) by Georges Davy and *La doctrine d'Émile Durkheim* (1916) and *Les Origines du sentiment religieux* (1925) by Maurice Halbwachs.

But the First World War brought tragedy to the Durkheimian school with the death of Émile Durkheim and his son André, as well as the loss of his young collaborators and students: Robert Hertz, Maxime David, Antoine Bianconni, etc. "Nous avons été privés de toute une génération de nos meilleurs et nos plus vigoureux collaborateurs […]. On verra que s'il n'y avait pas eu la guerre, la sociologie, la science, notre pays serait riche d'une œuvre comme peu d'études en ont produit de pareilles" [We were deprived of an entire generation of our best and most energetic collaborators. It will be seen that if the War had not taken place, sociology, science, our country would be rich with such an opus that few studies have produced to such a level] (Mauss, 1925). Marcel Mauss, the 'heir,' 'rekindled' *L'Année sociologique* but only two volumes were published in 1925 and 1927 with the participation of the 'old' collaborators of the first series: Marcel Mauss, Henri Hubert, Célestin Bouglé, François Simiand, Paul Fauconnet, and Maurice Halbwachs. In the first of the two volumes, Mauss published *In Memoriam* and his famous *Essai sur le don*.

In the 1930s, Durkheimians held three of the four chairs of sociology in French universities: Maurice Halbwachs at Strasbourg, and Paul Fauconnet and Bouglé at the Sorbonne. The fourth one, at Bordeaux, was held by Gaston Richard, a former Durkheimian. And Paul Lapie, then director of Primary Education, succeeded in introducing sociology into the curriculum of the *licence* (bachelor's) in philosophy. Durkheimian sociology saw a 'fresh' start with many activities and initiatives: creation of the Institut d'Ethnologie de Paris (1925), Marcel Mauss's election to the prestigious Collège de France (1930), the publication of the first volume of the new journal *Annales sociologiques* in 1934, and François Simiand's election to the Collège de France.

But, another 'dark' period came with the deaths of F. Simiand (1936), L. Levy-Bruhl (1939), and C. Bouglé (1940). And M. Halbwachs, elected to the Collège de France in 1943, passed away in 1945. Moreover, Marcel Mauss was ill; he died in 1950. This was, in a way, the end of the Durkheimian school, which had become the target of more frequent and very severe criticism in the 1930s and 1940s. Paul Nizan in *Les Chiens de garde* attacked Durkheim and his disciples, who were associated with the bourgeoisie and its conservative ideology (Nizan, 1932: p. 98). Jules Monnerot, a cofounder of the Collège de Sociologie and a friend of Georges Bataille and Roger Caillois, published in 1946 a book entitled *Les Faits sociaux ne sont pas des choses*, which was an epistemological critique of Durkheim's methodology. Finally, when Jean Stoezel came back from the United States after the War and gave his first lesson in sociology at Bordeaux, he concluded: "We should forget Durkheim" (Stoetzel, 1946).

But, Durkheim has not been forgotten. A well-known classical sociologist in the academic world, he has become the subject of a number of commentaries and theoretical interpretations. For instance, 6.3% of the 8353 articles published in the AJS and the ASR between 1895 and 1992 quote his texts. This is as many as Weber, the most influential sociologist of the era, who was quoted in 6.5% of the articles over the same period. So "[t]he knowledge of Durkheim and of his books is a full part of the definition of what a sociologist is in America" (Vogt, 1993: p. 227).

A first great intellectual biography of Durkheim was published by S. Lukes (1972). In addition, a 'rebirth' of all of Durkheim's texts took place in three volumes (Durkheim, 1975), edited by V. Karady, also the editor of three volumes of Marcel Mauss's *Oeuvres* (1969). Over the past 30 years, with the opening up of archives that have given us new data about Durkheim's life and work, Durkheimian studies have been growing rapidly, punctuated by the activities of Ph. Besnard in France, W.S. Pickering in England, R. Allen Jones in the United States, or M. Borlandi in Italy, and the publication of a new journal, *Études Durkheimiennes*, which became *Durkheimian Studies/Études Durkheimiennes*. Another sign of this rebirth is the multiplication of PhD theses, special issues of journals, a new intellectual biography of Durkheim (Fournier, 2007), and books on the French school of thought, mainly on Marcel Mauss: publication of the first intellectual biography of Mauss (Fournier, 1994), publication of his political texts, and creation of the *Revue du M.A.U.S.S.*

Finally, in Anglo-Saxon sociology, there has been not only a renewal of Durkheimian Studies (Alexander, l994; Cladis, 1992; Gane, 1992; Giddens, l986; Mestrovic, 1988; Schmauss, l994; Warfeild Rawls), but also the development of what we can call a Neo-Durkheimian perspective in sociology: three recent examples of this renewal are the 'strong program' of David Bloor (1976) and his colleagues in the sociology of science; the work of Randall Collins on violence in the sociology of interactions; and the work of Jeffrey Alexander (1996) and his research group in cultural sociology. Based on the 'reinterpretation' of *Elementary Forms of the Religious Life*, this renewal has given a central focus to the study of rituals (Bellah, 2005; Collins, 2004; Douglas, 1970/1982; Goffman, 1967) and to the 'rediscovery' of the idea of 'effervescence' (Alexander et al., 2006). Not only religion, but all social life can be seen as a sequence of rituals and more generally as a performance.

Editor's Note

Emile Durkheim was a well-known and articulate proponent of the 'new science' of sociology and enjoyed a coterie of collaborators and followers during his lifetime and, of course, thereafter. 'The Durkheimians' include both historical figures and a large group of present-day sociologists who proudly trace their work to Durkheim's path-breaking insights. The following bibliographic entry is meant both to document and celebrate the long and continuing influence of Durkheim's thought not just in sociology but in anthropology and allied disciplines as well.

Abstract

This section reviews a specialty within the field of decision making known as dynamic decision making. Dynamic decisions are characterized by a decision maker choosing among various actions at different points in time in order to control and optimize performance of a dynamic stochastic system. Realistic examples include fighting fires, navigational control, battlefield decisions, medical emergencies, and so on. The section has four parts. The first reviews basic theory concerning optimal decision principles in a dynamic context, the second summarizes empirical approaches to the study of human performance on dynamic decision tasks, the third presents theoretical models that describe how humans learn to control dynamic systems, and the last discusses methodological issues arising from the study of complex decisions including differences between field versus laboratory research.

Dynamic decision making (DDM) is defined by three common features: a series of actions must be taken over time to achieve some overall goal, the actions are interdependent so that later decisions depend on earlier actions, and the environment changes both spontaneously and as a consequence of earlier actions (Edwards, 1962). Dynamic decision tasks differ from sequential decision tasks (see Diederich, 2001) in that the former are primarily concerned with controlling dynamic systems over time, whereas the latter are more concerned with sequential search for information to be used in making decisions.

Psychological research on DDM began with Toda's (1962) pioneering study of human performance on a game called the 'fungus eater,' in which human subjects controlled a robot's search for uranium and fuel on a hypothetical planet. Subsequently, human performance has been examined across a wide variety of dynamic decision tasks including computer games designed to simulate stock purchases (Ebert, 1972; Rapoport, 1966), welfare management (Dorner, 1980; Mackinnon and Wearing, 1980), vehicle navigation (Jagacinski and Miller, 1978; Anzai, 1984), health management (Kleinmuntz and Thomas, 1987; Kerstholt, 1994), production and inventory control (Sterman, 1989; Berry and Broadbent, 1988), supervisory control (Kirlik et al., 1993a,b), firefighting (Brehmer and Allard, 1991; Brehmer and Nahlinder, 2007), prey and predator problems (Jensena and Brehmer, 2003), plumbing and cash flow tasks (Gonzalez and Dutt, 2011; Sweeney and Sterman, 2000), and farming on Mars (Gureckis and Love, 2009a). Cumulative progress in this field has been summarized in a series of empirical reviews by Edwards (1962), Rapoport (1975), Funke (1991), Brehmer (1992), Sterman (1994), Kerstholt and Raaijmakers (1997), and Jagacinski and Flack (2003).

Stochastic Optimal Control Theory

To illustrate how psychologists study human performance on dynamic decision tasks, consider the following experiment by You (1989). Subjects were initially presented a 'cover' story describing the task: "Imagine that you are being trained as a psychiatrist, and your job is to treat patients using a psychoactive drug to maintain their health at some ideal level." Subjects were instructed to choose the drug level for each day of a simulated patient after viewing all of a patient's previous records (treatments and health states). Subjects were trained on 20 simulated patients, with 14 days per patient, all controlled by a computer simulation program.

There are a few general points to make about this type of task. First, laboratory tasks such as this are oversimplifications of real-life tasks, designed for experimental control and theoretical tractability. However, more complex simulations also have been studied to provide greater realism (e.g., Brehmer and Allard's, 1991, firefighting task). Second, the above task is an example of a discrete time task (only the sequence of events is important), but real-time simulations have also been examined where the timing of decisions becomes critical (e.g., Brehmer and Allard's, 1991, firefighting task). Third, the cover story (e.g., health management) provides important prior knowledge for solving the task, and so the findings depend both on the abstract task properties as well as the concrete task details (Kleiter, 1975). Fourth, the stimulus events are no longer under complete control of the experimenter, but instead they are also influenced by the subject's own behavior. Thus experimenters need to switch from a stimulus–response toward a cybernetic paradigm for designing research (cf. Brehmer, 1992; Rapoport, 1975).

This health management task can be formalized by defining $H(t)$ as the state of the patient's health on day t; $T(t)$ is the drug treatment presented on day t, and $w(t)$ is a random shock that may disturb the patient on any given day. Figure 1 is a feedback diagram that illustrates this dynamic decision task. In this figure, S represents the environmental system that takes both the disturbance, w, and the decision maker's control action, T, as inputs, and produces the patient's state of health, H, as output. D represents the decision maker's policy that takes both the observed, H, and desired, H^*, states of health as inputs, and produces the control action, T, as output.

Figure 1 A feedback diagram of an example dynamic decision task.

Based on these definitions, this task can be analyzed as a stochastic linear optimal control problem (Rouse, 1980): determine treatments $T(1)$, …, $T(N)$, for $N = 14$ days, which minimize the objective function

$$F = E\left\{\sum_{t=1,N}\alpha[H(t) - H^*(t)]^2 + \beta T^2(t)\right\} \quad [1]$$

contingent upon the linear stochastic dynamic system,

$$\begin{aligned} H(t+1) = {} & a_1H(t) + a_2H(t-1) + b_1T(t) \\ & + b_2T(t-1) + b_3T(t-2) + w(t) \end{aligned} \quad [2]$$

Standard dynamic programming methods (Bertsekas, 1976) may be used to find the optimal solution to this problem. For the special case where the desired state of health is neutral ($H^* = 0$), some treatment effect takes place the very next day (b_1 is nonzero), and there is no cost associated with the treatments (i.e., $\beta = 0$), the optimal policy

$$\begin{aligned} T(t) = {} & -[(a_1/b_1)H(t) + (a_2/b_1)H(t-1) \\ & + (b_2/b_1)T(t-1) + (b_3/b_1)T(t-2)] \end{aligned} \quad [3]$$

is the treatment that forces the mean health state to equal the ideal (zero) on the next day. If the cost of treatment is nonzero (i.e., $\beta > 0$), then the solution is a more complex linear function of the previous health states and past treatments (see Bertsekas, 1976; You, 1989).

Dynamic programming is a general-purpose method that can be used to solve for optimal solutions to many dynamic decision tasks. Although the example above employed a linear control task, dynamic programming can also be used to solve many nonlinear control problems (see Bertsekas, 1976). However, for highly complex tasks, dynamic programming may not be practical, and heuristic search methods such as genetic algorithms (Holland, 1994) may be more useful.

The formal task analysis presented above provides a basis for determining factors that may affect human performance on the task (cf., Brehmer, 1992). One factor is the stability of the dynamic system, which for eqn [2] depends on the two coefficients, a_1 and a_2. In particular, this system is stable if the roots of the characteristic equation

$$\lambda^2 - a_1\lambda - a_2 = 0$$

are less than one in magnitude (see Luenberger, 1979). A second factor is the controllability of the system, which depends on the three coefficients, b_1, b_2, and b_3 (see Luenberger, 1979). For example, if the treatment effect is delayed ($b_1 = 0$), then the simple control policy shown in eqn [3] is no longer feasible, and the optimal policy is more a complex linear function of the system coefficients.

Consistent with previous research, You (1989) found that even after extensive experience with the task, subjects frequently lost control of their patients and the average performance of human subjects fell far below optimal performance. However, this is a gross understatement. Sterman (1989) found that when subjects tried to manage a simulated production task, they produced costs 10 times greater than optimal, and their decisions induced costly cycles even though the consumer demand was constant. Brehmer and Allard (1991) found that when subjects tried to fight simulated forest fires, they frequently allowed their headquarters to burn down despite desperate efforts to put the fire out. Kleinmuntz and Thomas (1987) found that when subjects tried to manage their simulated patients' health, they often let their patients die while wasting time waiting for the results of nondiagnostic tests and performed more poorly than a random benchmark.

Alternative Explanations for Human Performance

There are many alternative reasons for this suboptimal performance. By their very nature, dynamic decision tasks entail the coordination of many tightly interrelated psychological processes including causal learning, planning, problem solving, and decision making (cf. Toda, 1962). Six different psychological approaches for understanding human DDM behavior have been proposed, each focusing on one of the component processes.

The first approach was proposed by Rapoport (1975), who suggested that suboptimal performance could be derived from an optimal model either by adding information processing constraints on the planning process, or by including subjective utilities into the objective function of eqn [1]. For example, Rapoport (1966, 1967) found that human performance in his stock purchasing tasks was accurately reproduced by assuming that subjects could only plan a few steps ahead (about three steps), as compared to the optimal model with an unlimited planning horizon. In this case, dynamic programming was useful for providing insights about the constraints on human planning capabilities. As another example, Rapoport et al. (1970) attempted to predict performance in a multistage investment game by assuming that the utility function was a concave function of monetary value. In this case, Rapoport et al. (1970) used dynamic programming to derive an elegant decision rule, which predicted that investments should be independent of the size of the capital accumulated during play. Contrary to this prediction, human decision makers were strongly influenced by this factor, and so in this case, dynamic programming was useful for revealing empirical flaws with the theory.

An alternative approach, proposed by Brehmer (1992) and Sterman (1994), is that suboptimal performance is caused by a misconception of the dynamic system (eqn [2]). In other words, a subject's internal model of the system does not match the true model. In particular, human performers seem to have great difficulty discerning the influence of delayed feedback and understanding the effects of nonlinear terms in the system (Rahmandad et al., 2009). Essentially, subjects solve the problem as if it was a linear system that has only zero lag terms. In the case of eqn [2], the subjective decision policy is simply

$$T(t) = -c_1H(t)$$

where c_1 is estimated from a subject's control decisions. Sterman (1989) and Diehl and Sterman (1993) found that this type of simplified subjective policy described their subjects' behavior very accurately.

Several recent studies have investigated how to improve people's understanding of the dynamic systems in DDM tasks. Kopainsky and Sawicka (2011) used an interactive simulation tool, which allowed participants to explore the dynamic features of a resource management task. They found that the tool allowed decision makers to construct more accurate mental representations of the task, resulting in greater understanding and improved performance. Cronin, Gonzalez, and Sterman (2008) suggested that having participants verbalize their decisions enhanced their performance in an accumulator task. Sterman (2010) reported that training MIT graduate students in system dynamics (e.g., with an introductory system dynamics course) also improved their overall task performance.

A more general method for estimating subjective decision policies was proposed by Jagacinski (Jagacinski and Miller, 1978; Jagacinski and Hah, 1988). Consider once again the example problem employed by You (1989). In this case, a subject's treatment decision on each trial $T(t)$ could be represented by a linear control model:

$$T(t) = c_0 + c_1H(t) + c_2H(t-1) + c_3H(t-2) + c_4T(t) + c_5T(t-1) + c_6T(t-2) + \text{error}$$

where the subjective coefficients ($c_0, c_1, \ldots, c_6$) are estimated by a multiple regression analysis. This is virtually the same as performing a 'lens model' analysis to reveal the decision maker's policy (see Kleinmuntz, 1993; Slovic and Lichtenstein, 1971). This approach has been successfully applied in numerous applications (Jagacinski and Miller, 1978; Jagacinski and Hah, 1988; Kerlik, Miller, Jagacinski, 1993; Kleinman et al., 1980; You, 1989). Indeed, You (1989) found that subjects made use of both lags 1 and 2 for making their treatment decisions.

Heuristic approaches to strategy selection in dynamic decision tasks have been explored by Kleinmuntz (1985), Kleinmuntz and Thomas (1987), and Kerstholt (1994, 1996). These researchers examined health management tasks that entailed dividing time between two strategies: collecting information from diagnostic tests before choosing a treatment, versus treating patients immediately without conducting any more diagnostic tests. A general finding is that even experienced subjects tend to overuse information collection, resulting in poorer performance than that which could be obtained from a pure treatment (no test) strategy. This finding seems to run counter to the adaptive decision-making hypothesis of Payne et al. (1993), which claims that subjects prefer to minimize effort and maximize performance. The information collection strategy is both more effortful and less effective than the treatment strategy in this situation. In another study, Cronin et al. (2008) employed simple stock-flow problems and found that people's inability to understand the dynamics of the task resulted from their use of inappropriate heuristics, which sometimes yielded correct responses, but fundamentally misrepresented the interplay of task variables. Performance remained poor, regardless of the amount of data presented to the participants, the method of presentation, and changes to the cover stories or context.

Finally, an individual difference approach to understanding performance on complex dynamic decision tasks was developed by Dorner and his colleagues (see Funke, 1991 for a review). Subjects are divided into two groups (good versus poor) on the basis of their performance on a complex dynamic decision task. Subsequently, these groups are compared on various behaviors to identify the critical determinants of performance. This research indicates that subjects who perform best are those that set integrative goals, collect systematic information, and evaluate progress toward these goals. Subjects who tend to shift from one specific goal to another, or focus exclusively on only one specific goal, perform more poorly. Along these lines, Bisantz et al. (2000) applied the lens model to DDM tasks and found that much of the differences between the best and worst performers were due to the relative consistency with which top performers made judgments, and not to different judgment policies, nor to characteristics of the judgment environments.

Learning to Control Dynamic Systems

Although human performers remain suboptimal even after extensive task training, almost all past studies reveal systematic learning effects. First, overall performance often rapidly improves with training (see e.g., Brehmer, 1992; Gonzalez and Quesada, 2003; Mackinnon and Wearing, 1985; Rapoport, 1966; Sterman, 1989). Furthermore, subjective policies tend to evolve over trial blocks toward the optimal policy (Jagacinski and Miller, 1978; Jagacinski and Hah, 1988; You, 1989). Therefore, learning processes are important for explaining much of the variance in human performance on dynamic decision tasks (cf., Hagmayer et al., 2010; Hogarth, 1981). Three different frameworks for modeling human learning processes in dynamic decision tasks have been proposed (Osman, 2010).

A production rule model was developed by Anzai (1984) to describe how humans learn to navigate a simulated ship. The general idea is that past and current states of the problem are stored in working memory. Rules for transformation of the physical and mental states are represented as condition–action type production rules. A product rule fires whenever the current state of working memory matches the conditions for a rule. When a production rule fires, it deposits new inferences or information in memory, and it may also produce physical changes in the state of the system. Navigation is achieved by a series of such recognize–act cycles of the production system. Learning occurs by creating new production rules that prevent earlier erroneous actions, and new rules are formed on the basis of means–ends type of analyses for generating subgoal strategies. Simulation results indicated that the model learned strategies similar to those produced in the verbal protocols of subjects, although evaluation of the model was dependent on qualitative judgments rather than quantitative measurements.

An instance- or exemplar-based model was later developed by Dienes and Fahey (1995) to describe how humans learn to control a simulated sugar production task, and to describe how they learn to manage the emotional state of a hypothetical person. This model assumes that whenever an action leads to a successful outcome, the preceding situation and the successful

response are stored together in memory. On any given trial, stored instances are retrieved on the basis of similarity to the current situation, and the associated response is applied to the current situation. This model was compared to a simple rule-based model like that employed by Anzai (1984). The results indicated that the exemplar learning model produced more accurate predictions for delayed feedback systems, but the rule-based model performed better when no feedback delays were involved. This conclusion agrees with earlier ideas presented by Berry and Broadbent (1988) that delayed feedback tasks involve implicit learning process, whereas tasks without delay are based on explicit learning processes.

Gonzalez et al. (2003) proposed the more sophisticated instance-based learning theory (IBLT), which posits that decision makers adapt their judgment strategies from heuristic-based to instance-based as they accumulate and refine their knowledge and learn to recognize situations based on similarity to past instances. This model was used to explain data from a water distribution simulation. In the task, participants managed a water purification plant by shifting water between several tanks. As rain fell some tanks spontaneously filled with water and had to be pumped. IBLT construes the decision maker as learning to control this DDM task through the accumulation and refinement of instance-based knowledge. Participants begin by operating according to simple, domain-general heuristics. However, as decision makers gain experience in the task, they accumulate instance knowledge that can be used to improve performance.

Figure 2 gives a graphical representation of how the model performs a DDM task. The process begins with a search through memory for instances that match the current state. Instances are represented as situation–decision–utility (SDU) triplets, which code environmental cues, the decision made in that environment, and the utility of the experienced outcome. SDUs are retrieved based on the similarity between the current state and each instance in memory. If no sufficiently similar instances are found, a heuristic is used to choose an action. If a similar entry is found in memory, the model must decide whether to search for more alternatives or to execute the current best action. Additional alternatives are evaluated until one exceeds the decision maker's aspiration threshold or time runs out before a decision deadline, at which point the action with the highest utility is chosen. After executing an action, memory is updated. New SDUs are accumulated as more alternatives and more decision situations are confronted. Over time, the model is able to use more and more diagnostic cues to search its growing memory. Feedback on previous actions is used to update the utilities of the SDUs. With experience, the model transitions away from heuristic-based decisions as it adapts to the dynamic environment. Gonzalez et al. (2003) tested several versions of IBLT and found that the full version captured participants' changes in performance as they moved away from random or heuristic-based decisions, toward instance-based strategies. Gonzalez and Dutt (2011) used IBLT to model subjects' behavior in two different versions of a decision-from-experience task. Sampling and repeated-choice paradigms are often thought to rely on differences in psychological mechanisms, but IBLT was able to account for choices in both scenarios using a common set of cognitive mechanisms.

Gibson et al. (1997) used an artificial neural network model to describe learning in a sugar production task. This model receives input representing the current state of the environment and the current goal for the task. Hidden layers compute the next action and predict its consequences. Connections between hidden layers and input and output layers are learned by back propagating prediction errors and deviations between observed outcomes and the goal state. This model provided good accounts of subjects' performance during both training and subsequent generalization tests under novel conditions. Recently, Gibson (2007) extended this model by assuming that decision makers first sort their evidence into categories before weighting and using the sorted evidence. This two-stage model better predicted decision makers' performance in a new, related bargaining task. Unfortunately, no direct comparisons with rule- or exemplar-based learning models were conducted, and this remains a challenge for future research.

Another approach to modeling the learning of dynamic systems is the reinforcement learning model (see Sutton and Barto, 1998, for a review of this approach). The goal of this algorithm is to maximize the future cumulative reward through interacting with the environment. Consequently it does not need to know the model of the environment or the correct input/output pairs (as in supervised learning). Optimization is based on the agent's online samples from the environment.

Figure 2 IBLT model diagram.

Recently, Gureckis and Love (2009b) used model-based reinforcement learning to examine human behavior in a 'Farming on Mars' task. Participants' goal was to use two Martian robots to establish oxygen for later human residents. Only one robot could be used at a time, and each performed differently. Participants had to learn about each robot's oxygen output through experience. When rewards were generated probabilistically based on subjects' choices, Gureckis and Love found that decision makers preferred the robot with high short-term output but low long-term output. In the continuous reward condition, where rewards were a deterministic function of subjects' choices, decision makers preferred the robot with the better long-term output but worse short-term output.

In another study, Gureckis and Love (2009a) examined noise effects by implementing noise on both rewards and representations of the current state of task. They found that some moderate level of reward noise caused participants to explore different strategies and helped them find the optimal policy among their alternatives. However, noisy state cues decreased performance relative to no noise conditions. It seems that decision makers use state information as support for their decisions, and so noisy state information is more harmful than noisy reward. Continuing with the 'Farming on Mars' task, Otto and Love (2011) used a reinforcement learning framework to model the impacts of forgone rewards on DDM. They found that providing more information about what could have been gained at each point interfered with subjects' capability to make long-term choices.

Laboratory versus Naturalistic Decision Research

Klein and his associates (Klein et al., 1993; Klein, 2008; Lipshitz et al., 2001; Zsambok and Klein, 1997) have made progress toward understanding dynamic decisions in applied field research settings, which they call naturalistic decision making (e.g., interview fire chiefs after fighting a fire). Field research complements laboratory research in two ways: on the one hand, it provides a reality check on the practical importance of theory developed in the laboratory; on the other hand, it provides new insights that can be tested with more control in the laboratory.

The general findings drawn from naturalistic decision research provide converging support for the general theoretical conclusions obtained from the laboratory. First, it is somewhat of a misnomer to label this kind of research 'decision making' because decision processes comprise only one of the many cognitive processes engaged by these tasks – learning, planning, and problem solving are just as important. Decision making is used to define the overall goal, but then the sequence of actions follows a plan that has either been learned in the past or generated by a problem-solving process. Second, learning processes may explain much of the variance in human performance on dynamic decision tasks. Decision makers use the current goal and current state of the environment to retrieve actions that have worked under similar circumstances in the past. Klein's (1998) recognition-primed decision model is based on this principle, and this same basic idea underlies the production rule, exemplar, and neural network learning models. Third, learning from extensive experience is the key to understanding why novel subjects fail where experts succeed. A few hundred trials in a laboratory task are relatively insignificant in comparison with say 25 years of experience on a job. Naïve subjects may fail to prevent their headquarters from burning down in a simulated forest fire, but expert fire chiefs succeed in saving our national parks from forest fires every year.

This article is a revision of the previous edition article by D. Dransch, volume 6, pp. 3908–3911, © 2001, Elsevier Ltd.

Abstract

Dynamic mapping summarizes various cartographic presentation methods that incorporate the dimension of time in a map. The methods can be differentiated according to the way they encode the dimension of time: time is either presented by visual encodings in a map, by a spatial dimension, by time, or by a combination of multiple views.

Dynamic mapping is a cartographic concept used to depict dynamic spatial phenomena such as change of land use, spread of diseases, or bird migration. It summarizes various visualization methods that incorporate the dimension of time into a map.

These methods utilize different strategies: temporal information is graphically encoded within the map, time is mapped on an additional spatial dimension, time is presented by animation, or a combination of multiple views is used. Each of these methods has unique individual characteristics and thus is suitable for specific tasks (Figure 1).

The Term and Concept of Dynamic Mapping

Dynamic mapping is a visualization concept that is involved with the depiction of spatial processes on maps. Our world is constantly changing. If changes are of little interest, it is sufficient to present a specific state of our world and of the corresponding date. Yet, if occurring changes are of great importance, the dynamic aspect of reality – the dimension of time – has to be depicted in maps. Various presentation methods have been developed to give an impression of the changes and movements in space (Monmonier, 1990; Muehrcke, 1992). The methods can be differentiated into three main groups according to the way they encode the dimension of time: time is either presented by visual encodings in a map, by a spatial dimension, or by time. If dynamic mapping is related to a computer device, interactive visualization can be applied that facilitates multiple views on the presented changes and processes (Andrienko et al., 2010).

Presenting Time by Visual Encodings in a Map

The most common way to visualize dynamic spatial phenomena is to represent them by visual encodings in a map. Temperature curves of several measurement stations, maps of

Figure 1 Methods to depict spatial processes.

urban growth, or maps of land use change are well known examples. In general, the following types of maps can be differentiated, each applying a different strategy to communicate dynamic aspects: time-series maps, time-composite maps, change maps, map with time-related charts, and vector or flow maps.

Time-series maps, also called small multiples, show one spatial area for different points in time in a series of maps (Figure 1(a)). The user has to compare the individual maps to understand changes between single states. To facilitate this task, time-series maps have to be arranged in a way that enables visual comparison. They have to be placed next to each other, and their content should not be too complex. Map series are commonly applied to show the distribution of particular phenomena at given intervals, e.g., changes of population distribution, boundaries, or landuse, etc.

Another method is the time-composite map (Figure 1(b)). Such a map depicts two or more stages of a dynamic phenomenon in one single map. The distinct stages can be differentiated by color, pattern, isolines, or point symbols. Time-composite maps are suitable for showing the expansion or contraction of areas, linear networks, or other dynamic phenomena, e.g., the growth of a city, the development of transportation systems, or the spread of diseases. Time-composite maps succeed in presenting one-directional changes, but they fail if retrogressive developments have to be depicted as an intermediate stage.

Time series and time-composite maps show selected stages of the entire development. The change itself has to be understood by interpretation. However, some geographical questions emphasize, above all, the change and its extent. These questions require a map, which shows explicitly the change that has taken place within a certain time period. For that purpose the change map was developed (Figure 1(c)). Qualitative change maps depict objects that have been added to or removed from a particular area during a relevant time period, e.g., the difference in forest cover in different years. Quantitative change maps present changes in magnitude, the change in a value such as population density or air pollution. They either show the direction of change as increase or decrease, or give the absolute values of magnitude change.

A further method of presenting changes directly is a map with time-related charts (Figure 1(d)) that depicts dynamic phenomena of areas or locations in line or bar graphs, e.g., maps with diagrams of the annual temperature curve for selected stations. This type of map is able to give a detailed impression of development in time, but it is delimited in its ability to depict the spatial distribution of a changing phenomenon.

Geographical processes may take place at a particular location (similar to the mentioned changes of population or temperature) or they may be a sort of movement in space like the movement of people, goods, or winds. To show these spatial movements, vector or flow maps with special symbols such as arrows or lines are applied (Figure 1(e)). Position and alignment of arrows and lines can depict the moving objects' routes and directions, and the size of the signatures can denote the objects' values. Typical examples of vector or flow maps are maps of expedition routes, commuter movements, or ocean currents.

Presenting Time in a Space–Time Cube

The space–time cube is yet another method of visualizing spatial changes over time (Kraak, 2008). It originates from space–time concepts that were developed in the 1960s. This approach maps space and time onto the three axes of a cube; the x- and y-axes represent the geographical dimension; time is mapped to the third dimension (Figure 1(f)). The result is a three-dimensional presentation of a space–time continuum. Space–time cubes are increasingly applied to visualize trajectories, movement lines created for instance by people, animals, or the spreading of diseases. As time is mapped onto a quantitative axis, time duration to cover a distance becomes apparent; the cube unveils movement patterns in space and time. A further advantage of the three-dimensional cube is to facilitate presenting even back and forth movements without graphical clutter. Although presentation of trajectories is the main application of the space–time cube, it is a proper visualization method for all geographical phenomena changing in space and time.

Presenting Time by Time: Cartographic Film and Animation as Dynamic Maps

All presentation methods referred to above are able to produce an idea regarding the changes that take place, but they do not provide an intuitive depiction of the dynamics of a process. To overcome this shortcoming cartographic films or animations were introduced. They are sequences of slightly varying maps that create an illusion of continuous spatial movement or change (Figure 1(g)). By mapping real time to presentation time they vividly show the dynamics of a process. They also allow for making apparent time intervals of either extremely long or short duration utilizing fast or slow motion. Early cartographic films were produced for military propaganda to depict frontier changes during World War II, or as instruction material for students; each map of the sequence was drawn by a cartographer. Because of their time-consuming and expensive production, hand-made cartographic films did not become a widespread presentation form. This has changed with the advent of powerful computer technology, which has greatly facilitated the creation of animated films. Computer animation can further be enhanced with user interaction. At a basic level, the user is enabled to start, stop, interrupt as well as to delay or accelerate an animation. At a higher level, more sophisticated interactions allow for selecting particular time intervals or determining different viewpoints (Dransch, 1997).

Multiple Views

As an alternative to the above-discussed visualization methods, spatial and temporal aspects can be separated into multiple views. Usually a map is combined with a presentation of temporal data in a time-related chart, such as a time-value plot or a bar chart (Figure 1(h)). When combining such distinct visual representations, it is important to convey the linkage between data in the map and data in the temporal display. Visual linking, for example by using consistent colors or labels

in both presentations, can fulfill this purpose. Yet, multiple views unfold their strength in interactive environments. Here, they can be combined with interaction methods such as brushing and linking, which highlights selected data in both views simultaneously. Additionally, it is possible to follow an overview and detailed concept. As an example, the map might serve as an overview of all locations, whereas a time-related chart might show details about dynamic developments for selected locations. The other way around, a time-related chart can provide an overview of the dynamics of a phenomenon, and the map may depict the spatial distribution at a selected time point.

In this sense, the concept of multiply coordinated views is highly flexible and allows depicting both spatial and temporal developments in detail. The ability to analyze data step by step in high detail is beneficial when the amount of data is too large to be shown at once and the display of few temporal stages is not sufficient. Exemplary of such data are temperature curves over a long time period, which need to be analyzed on a daily basis rather than by monthly or yearly aggregates.

Dysexecutive Amnesia

Abstract

Memory impairments can result from frontal lobe damage, and because the frontal lobes perform executive functions, these impairments have been referred to as dysexecutive amnesia. Memory disturbances most commonly associated with dysexecutive amnesia include a disproportionate impairment in recall, deficient temporal ordering, source amnesia, and impaired metamemory. Components of dysexecutive amnesia are often observed in patients with Korsakoff's amnesia, vascular thalamic amnesia, anterior communicating artery aneurysms, and in memory impairments associated with schizophrenia. We summarize evidence that the frontal lobes play a role in normal memory and that damage to the frontal lobes can cause dysexecutive memory impairments.

Introduction

Amnesia refers to memory loss and is most commonly associated with damage to the hippocampus and the medial temporal lobes. However, amnesic impairments also accompany damage to other brain structures, including the frontal lobes, the thalamus, and pathways that interact with the hippocampus (i.e., the mammillothalamic tract). We apply the term 'dysexecutive amnesia' to describe memory impairments associated with frontal dysfunction and those that therefore have a strong executive component, while noting that the literature generally lacks a consistent terminology to refer to these impairments. We also focus on particular disorders that are associated with dysexecutive memory impairments in an effort to summarize and characterize dysexecutive amnestic disturbances.

Amnesia can affect memory for past events or new learning. The inability to remember past events is termed retrograde amnesia, whereas the inability to form new memories is termed anterograde amnesia. Amnesia tends to affect the declarative memory system or information that is available to conscious awareness. In contrast, amnesics tend to have preserved nondeclarative (implicit, procedural) memory, which is less available to consciousness. Spared implicit memory is evident in the ability of amnesics to perform previously learned procedural skills and to acquire new ones even though they have no recollection of the learning episodes. As noted, amnestic disorders most commonly originate from disruption of medial temporal lobe function. However, given the numerous contributions of the frontal lobes to memory, frontal lobe dysfunction can also lead to deficits of memory.

The frontal lobes are involved in higher-level cognitive processes, such as planning, sequencing, monitoring, inhibiting, resolving interference, and maintaining task goals. These functions are commonly termed cognitive control or executive control and are implemented by various regions of the prefrontal cortex. Executive control processes interact with the medial temporal lobe system to promote efficient and strategically controlled memorial processing (Moscovitch, 1992; Simons and Spiers, 2003; Dickerson and Eichenbaum, 2010). For example, executive control allows for self-initiated top-down control of encoding processes based on one's current task goals. Moreover, the frontal lobes assist with memory retrieval, by elaborating on encountered retrieval cues, for example. Additionally, the frontal lobes monitor the products of retrieval operations and determine if the memories satisfy relevant criteria. Thus, the frontal lobes contribute to the encoding, retrieval, and monitoring of long-term memories to promote successful veridical memory.

In addition to supporting long-term memory, the dorsolateral prefrontal cortex is involved in working memory, which allows for the short-term storage and manipulation of information held in mind. Numerous studies have shown that the dorsolateral prefrontal cortex is important for accurate working memory. The frontal lobes also enable the assessment of current and future memory performance (e.g., Shimamura et al., 1991), and this awareness of one's own memory is termed metamemory. Accurate metamemory allows for the efficient prediction of what will be remembered in the future and also enables the implementation of control processes to enhance memory. For instance, people can monitor if they will have difficulty remembering what they are encoding and can strategically decide to devote more time to studying that information.

The frontal lobes are interconnected with the medial temporal lobe system, both structurally and functionally. In particular, the mammillothalamic pathway connects the frontal cortex and the hippocampi. Functional associations between the frontal and medial temporal lobe regions during memory encoding and retrieval have been well documented with neuroimaging methods, which indicate the importance of frontal control processes in successful memory performance.

Dysexecutive Amnesia

Patients with frontal lobe damage frequently exhibit amnestic disturbances, which we describe in detail in the following section. However, note that, although memory impairments are common, restricted frontal damage does not produce the extensive amnestic syndromes that characterize temporal lobe lesions. Furthermore, although the term dysexecutive amnesia is not yet widely used, the term is applied here to characterize memory deficits associated with frontal damage or to describe

 http://dx.doi.org/10.1016/B978-0-08-097086-8.51029-0

memory disturbances in patients with other frontal-like symptoms. As such, dysexecutive amnesia is synonymous with frontal amnesia, frontal memory impairment, and dysexecutive memory impairment. Dysexecutive amnesia is also related to dysexecutive syndrome, which encompasses all executive impairments associated with frontal damage. Baddeley and Wilson (1988) explain that frontal amnesia may be a combination of classic amnesia coupled with dysexecutive symptomatology. Thus, dysexecutive amnesia specifically refers to the memory impairments associated with frontal pathology.

Common Dysexecutive Amnesia Memory Impairments

Impaired Recall

Patients with frontal lobe damage typically display anterograde amnesia, with a disproportionate impairment in free recall and relatively spared recognition memory (e.g., Jetter et al., 1986; Hanley et al., 1994; Eichenbaum et al., 2010; see Swick and Knight, 1999 for spared recognition in frontal patients). For instance, Jetter et al. (1986) tested patients with left, right, or bilateral frontal damage on free recall, cued recall, and recognition, and compared their performance to a nonfrontal patient control group. The frontal group displayed severely impaired free recall, which was strikingly low compared to their spared cued recall and spared recognition. The disproportionate impairment in free recall compared to cued recall and recognition suggests that the patients successfully encoded the information, but that they had particular difficulty self-initiating retrieval of these memoranda at test. Numerous studies replicate this disproportionate impairment in recall. Nevertheless, there are reported case studies of frontal patients with impaired recognition and spared recall (Delbecq-Derouesné et al., 1990), impaired recognition memory (Baddeley and Wilson, 1988), or no discrepancy between recall and recognition (Kopelman and Stanhope, 1998). Additionally, Shimamura et al. (1991) report that, compared to healthy controls, frontal patients were unimpaired on several tests of new learning, including paired-associate recall, story recall, and recall of the Rey–Osterrieth Complex Figure, although recall of unrelated word lists was disproportionately impaired.

Impaired free recall of previously learned information in dysexecutive amnesia is attributed to deficits associated with frontal lobe contributions to the strategic retrieval of information and to the utilization of self-generated retrieval cues (Moscovitch, 1992; Simons and Spiers, 2003). Moreover, executive deficits likely also contribute to poorer encoding strategies during new learning, which yield weaker memory representations (Moscovitch, 1992; Simons and Spiers, 2003). Furthermore, there is evidence that frontal patients have difficulty with both new learning and retrieving past events. D'Esposito et al. (1996) report that patients with frontal lesions had more severe retrograde amnesia than patients with basal forebrain lesions. Moreover, Della Sala et al. (1993) found that patients with prefrontal lesions exhibited deficient autobiographical memory retrieval, and that this impairment was correlated with performance on tasks tapping executive function. These results suggest that frontal patients have difficulty efficiently implementing executive control strategies to strategically encode and retrieve new or stored memories.

Temporal Discrimination Impairment

Frontal lobe patients also have difficulty keeping track of the temporal order of events (e.g., Huppert and Piercy, 1976; Milner et al., 1991; Shimamura et al., 1990). For instance, Milner et al. (1991) had frontal patients and healthy controls perform recency discriminations in a serial list-learning task that required participants to report which of the two simultaneously presented items they had seen most recently. Patients with damage to the midlateral frontal cortex were especially impaired on these temporal order judgments. Furthermore, Shimamura et al. (1990) asked frontal patients to reproduce the list of 15 words they had studied, maintaining the proper temporal order. Frontal patients were significantly impaired at arranging these words correctly compared to controls. These are just a few of the many studies indicating that memory for temporal order is consistently impaired with frontal damage.

Source Amnesia

Source amnesia also tends to accompany frontal lobe damage, as it is difficult for frontal patients to determine the context in which they initially encountered information. Janowsky et al. (1989b) tested frontal patients, older age-matched controls, and younger adult controls on memory for facts and memory of the sources of these facts. Despite comparable recall and recognition of the facts, frontal lobe patients made significantly more source errors than both control groups after a delay of 6–8 days. During shorter delays of either 5 min or 2 h, both frontal patients and older adult controls made more source errors than younger adults, which supports evidence of frontal decline in normal aging. Furthermore, Schacter et al. (1984) found that the number of source memory errors that their patients exhibited was correlated with poor performance on tasks sensitive to frontal lobe function. Neuroimaging studies also link source memory with the frontal lobes. This evidence along with the high incidence of source memory errors in frontal patients and older adults suggests a role of the frontal lobes in contextual source memory. As Janowsky et al. (1989b) explain, frontal lobe patients' impaired temporal ordering may contribute to their source memory deficit, as source memory also necessitates retrieval of temporal context.

Confabulation

Confabulation occurs when individuals make up stories or explanations to account for gaps in their memory. Confabulation is often referred to as 'honest lying' because the individuals genuinely believe the tales they are spinning. Confabulation is associated with damage to the ventromedial frontal lobes, and it most commonly involves inaccurate accounts of episodic memory (Schacter and Curran, 1995; Turner et al., 2008). Confabulation may be due to poor

strategic retrieval and monitoring processes, such that frontal patients may have difficulty searching memory, retrieving pertinent information, and determining if the memory they retrieved is applicable to the current situation or not (Moscovitch, 1992; Schacter and Curran, 1995). Importantly, Baddeley and Wilson (1988) state that confabulation differentiates frontal amnestic patients from nonfrontal amnestic patients. Thus, confabulation seems to be a unique symptom of dysexecutive amnesia.

Impaired Working Memory

The frontal lobes are also associated with working memory, or actively holding and manipulating information in mind over a short delay. Although amnesia typically describes deficits in long-term memory, impairments in working memory can occur, and in the case of dysexecutive amnesia, deficient working memory is often observed. Frontal patients often have difficulty performing delayed-response tasks in which they have to maintain information in mind over a short delay before making a response. D'Esposito and Postle (2002) report that frontal patients were impaired compared to controls on three of nine delayed-response experiments without distraction and four of six experiments with distraction. Furthermore, in an early study Jacobsen (1936) demonstrated that monkeys with bilateral frontal lesions had impaired delayed-response task performance, such that they were not able to maintain the location of a food reward in mind after a screen occluded the cups. Additionally, single-cell recordings from neurons in the prefrontal cortex of monkeys revealed cells that maintained location-specific information over a delay (Funahashi et al., 1990). These single-cell recordings provide evidence that neurons within the prefrontal cortex are responsible for maintaining location-specific information over a delay period. Critically, however, frontal patients typically display spared simple memory span (e.g., Baddeley and Wilson, 1988; D'Esposito and Postle, 2002; but see Shimamura et al., 1991 for evidence of impaired digit span in frontal patients). Dysexecutive amnesia, thus, can involve impairments in working memory, but does not always affect simple short-term memory span.

Metamemory Impairment

Individuals with frontal amnesia not only have memory impairments, but they also often have metamemory problems, such that they are unaware of the extent of their memory disturbances and are unable to accurately predict their future memory performance (e.g., Jacobson and Lishman, 1990). For instance, even when cued recall levels were matched between frontal amnesics and temporal amnesics, frontal patients exhibited larger discrepancies between their feeling of knowing ratings and their true memory performance than did temporal amnesics (Janowsky et al., 1989a). Moreover, Kopelman et al. (1998) compared subjective evaluations of memory performance for patients with frontal, diencephalic, and temporal lesions, and they found that both frontal and diencephalic patients exhibited impaired metamemory. Thus, unlike temporal amnesics, frontal and diencephalic amnesics had poor awareness of their memory problems. These metamemory impairments may contribute to the memory disturbances that are observed in frontal patients because a lack of insight into the severity of their memory impairments can preclude the engagement of compensatory strategies to mitigate their memory deficits.

Susceptibility to Proactive Interference

Dysexecutive amnesics also tend to be especially susceptible to proactive interference and do not show the typical release from proactive interference when the category of memoranda is changed. Moscovitch (1982) found that patients with a left frontal lobectomy had the smallest release from proactive interference, and that Korsakoff's patients had similarly impaired release from proactive interference (see also Squire, 1982; Shimamura et al., 1991). Strikingly, in contrast, amnesics with left temporal and hippocampal damage displayed a normal release from proactive interference. Moscovitch cites this differing susceptibility to proactive interference as a fundamental characteristic that distinguishes frontal amnesics from temporal/hippocampal amnesics. Note, however, that Shimamura et al. (1991) found a normal release from proactive interference in their sample of frontal patients.

Increased False Alarms

Among the more commonly reported deficits associated with frontal damage is an increased false alarm rate. Patients with frontal lesions tend to produce many intrusions in free recall tests and tend to have high false alarm rates in recognition memory tests (e.g., Schacter and Curran, 1995; Parkin et al., 1996; Swick and Knight, 1999; Eichenbaum et al., 2010). Recently, Eichenbaum et al. (2010) report that prefrontal damage results in deficient recollection that manifests partly in disproportionately large rates of false alarms. In an earlier case study, Schacter and Curran (1995) report that patient J.B., who suffered frontal lobe damage following the rupture of an anterior communicating artery aneurysm, had high false recognition rates, as well as high confidence in this false recognition. Poor executive monitoring processes may contribute to these high intrusion rates. Additionally, impairments in source monitoring may preclude frontal patients from considering why something is familiar to them, thus causing them to mistake semantic relatedness for prior list inclusion, for example.

Perseveration

Perseveration, a common sequela of frontal lobe damage, entails the repetition of responses that are no longer relevant. Perseveration can be observed on the Wisconsin Card Sorting Test when patients erroneously sort cards by a previously relevant rule rather than adjusting their performance to the new feedback. Although perseveration is more classically an executive impairment, perseveration can also affect memory performance when previously relevant information erroneously intrudes during recall. Patients with frontal damage often exhibit perseveration (Baddeley and Wilson, 1988; Shimamura

et al., 1991; Parkin and Leng, 1993; Rolls et al., 1994), and this dysexecutive impairment can interfere with accurate memory performance.

Impaired Frequency Judgments

Related to their impairment in source memory and temporal memory, individuals with frontal damage are also deficient in frequency judgments. Stanhope et al. (1998) had frontal, temporal, and diencephalic lesion groups judge the frequency of occurrence of abstract patterns, and found that all three groups produced impaired estimates. These results suggest that, although not solely attributable to dysexecutive amnesia, individuals with damage to the frontal lobes have difficulty remembering the frequency with which they encountered something in the environment. The authors posit that frontal patients struggled with frequency judgments because they had difficulty monitoring their memory for the number of times they encountered that particular stimulus, which highlights again how an executive control deficit could contribute to poor memory performance.

Impaired Emotion-Based Learning

The impairments discussed thus far are primarily associated with damage to the lateral prefrontal cortex, regions thought to underlie more classically cognitive executive functions. However, damage to the orbitofrontal prefrontal cortex tends to be associated with socially inappropriate behaviors and impaired emotion-related learning. This was documented, for example, by Rolls et al. (1994), who found that patients with ventral frontal lesions displayed perseverative errors and continued responding toward the previously rewarded stimulus. Furthermore, the relative success or failure at learning reward mappings on these tasks was correlated with the degree of the socially inappropriate behavior that was displayed, which may be indicative of the extent of orbitofrontal damage. Ventromedial prefrontal lesions have also been associated with impaired learning on the Iowa Gambling Task (e.g., Bechara et al., 1996). In these tasks, unlike healthy control groups, patients with prefrontal lesions are not able to learn to avoid drawing cards from the risky deck that is associated with long-term monetary losses. Prefrontal patients also fail to generate anticipatory galvanic skin responses that control subjects exhibit when considering a risky deck selection. Thus, emotion-related memory impairments can be observed in cases involving lesions of ventromedial/orbitofrontal cortex.

Remedies

Although the memory disturbances associated with dysexecutive amnesia are vast, certain efforts can be taken to improve memory in these patients. As discussed previously, frontal patients have difficulty planning and generating strategies. Thus, external strategies and cues when provided for these patients have proven effective to improve encoding and to facilitate retrieval. We describe several successful interventions in the following paragraphs.

To start, although dysexecutive amnesics typically display impaired free recall, Jetter et al. (1986) found that frontal patients performed normally on cued recall. Simply providing categorical cues about the studied memoranda aided memory retrieval for these frontal patients. These results indicate that by providing sufficient external retrieval cues, frontal amnesics may be better able to recall what they have learned. Furthermore, Baddeley and Wilson (1988) found that providing detailed retrieval instructions improved word fluency in a frontal patient case study. Although this patient had extreme difficulty with word fluency when given the standard instructions (i.e., name as many animals as you can in a minute), being unable to produce a single word, with more specific instructions (i.e., name as many animals as you can that begin with the letter 'c' in a minute), this patient's performance dramatically improved. These studies suggest that detailed instructions with more specific retrieval cues can constrain the response options enabling frontal patients to overcome their difficulty with self-generated retrieval, and Thompson-Schill et al. (1997) suggest that such cues overcome the increased selection interference that can plague some frontal patients.

Likewise, because dysexecutive amnesics have difficulty generating their own strategy when confronted with a new task, their performance can be improved when strategy instruction is provided. Parkin et al. (1988) demonstrated this by instructing frontal lobe patients to use a mental imagery strategy during a paired associate-learning task, which then enhanced their memory performance. Similarly, Diamond et al. (1997) found that providing frontal patients with an organizational strategy at encoding improved their ability to reproduce the Rey–Osterrieth Complex Figure.

Finally, providing a clear and distinctive external structure when the patients encounter the memoranda can aid memory performance. Specifically, Kopelman and Stanhope (1998) found that frontal patients had better memory when the stimulus materials were organized by category, as opposed to when the materials were ordered randomly. Moreover, Winocur and Kinsbourne (1978) demonstrated that when patients studied paired-associates in the presence of a contextually rich environment (i.e., with colored lights and classical music playing in the background), they had better memory.

In sum, these studies demonstrate that providing detailed retrieval cues, external encoding strategies, and distinctive environmental cues can serve to lessen the severity of the memory impairments experienced by dysexecutive amnesics.

Disorders Associated with Dysexecutive Amnesia

Apart from focal frontal lobe lesions of vascular or traumatic origin, a wide array of disorders and syndromes can result in damage to the frontal lobes or in damage to pathways that connect the frontal lobes and medial temporal lobes. Here, we describe several disorders that are frequently associated with frontal lobe pathology. Consequently, individuals with these syndromes commonly display symptoms characteristic of dysexecutive amnesia. Although this section does not cover all of the possible syndromes that could result in frontal damage,

it summarizes key disorders most often accompanied by components of dysexecutive amnesia.

Vascular Thalamic Amnesia

Vascular thalamic amnesia occurs following damage to the thalamus and can result in the presentation of various dysexecutive amnesia symptoms. Carlesimo et al. (2011) recently reviewed reports of vascular thalamic amnesia to characterize specific thalamic lesion locations and their associated memory impairments. They found that damage to the mammillothalamic tract, in particular, predicted the presence of memory deficits in patients with thalamic lesions. Because the anterior nucleus of the thalamus is part of the mammillothalamic tract that sends projections to the hippocampus and mammillary bodies via the fornix, the anterior nucleus of the thalamus is implicated as a critical component that supports normal memory function.

Carlesimo et al. (2011) reviewed data from 83 patients with vascular thalamic lesions and carefully characterized the commonly reported memory disturbances. The authors explain that, like amnesics with medial temporal damage, thalamic amnesics tend to have impaired declarative anterograde amnesia, occasionally impaired declarative retrograde amnesia, spared implicit memory, and spared short-term memory. However, notably, unlike amnesics with temporal damage, vascular thalamic amnesics also tend to display dysexecutive symptoms observed in frontal patients. For instance, they are frequently impaired in set shifting, as indexed by impaired performance on the Trail-Making tests and the Wisconsin Card Sorting Test. Furthermore, these patients tend to have impaired inhibition on the Stroop test and impaired verbal fluency. In addition to these primarily cognitive dysexecutive deficits, Carlesimo et al. (2011) also report altered emotion in vascular thalamic patients, similar to the altered emotion seen in those with frontal damage. In particular, patients can display apathy and dysphoria whereas others can display mania. These findings indicate vascular damage to the mammillothalamic tract can result in memory impairments similar to those evident in patients with frontal lobe damage.

Korsakoff's Amnesia

Korsakoff's amnesia is a memory disturbance caused by thiamine deficiency that results in damage to the mammillothalamic tract. Chronic alcoholism can lead to thiamine deficiency, which explains why Korsakoff's amnesics are typically chronic alcoholics. Similar to vascular thalamic amnesics who have damage to the anterior nucleus of the thalamus and the mammillothalamic tract, Harding et al. (2000) found that damage to the anterior nucleus of the thalamus differentiates alcoholics with and without amnesia. Thus, Korsakoff's amnesia is also associated with damage to this pivotal pathway.

Korsakoff's amnesics display many similar memory impairments as frontal patients. As such, Korsakoff's patients could be considered a subclass of patients who experience dysexecutive amnesia. Korsakoff's amnesics have marked difficulty with temporal memory (Huppert and Piercy, 1976; Squire, 1982; Meudell et al., 1985), which is a characteristic symptom of dysexecutive amnesia. In fact, Squire (1982) found a correlation between the severity of Korsakoff patients' frontal symptoms and their performance on a temporal memory task. Furthermore, like individuals with frontal lesions, Korsakoff's patients tend to confabulate (Jacobson and Lishman, 1990), show metamemory impairments (Shimamura et al., 1991), exhibit impaired recall despite spared recognition (e.g., Huppert and Piercy, 1976), perseverate (Jacobson and Lishman, 1990; Shimamura et al., 1991), and they fail to show a release from proactive interference (e.g., Moscovitch, 1982; Squire, 1982; Shimamura et al., 1991). The pattern of impairments found in Korsakoff's patients suggests the memory deficits they suffer from are dysexecutive amnesia.

Rupture of Anterior Communicating Artery Aneurysm

The anterior communicating artery forms part of the Circle of Willis on the ventral surface of the brain, and it is one of the avenues of blood supply to the frontal lobes. When an aneurysm of the anterior communicating artery ruptures, or when an aneurysm has to be surgically repaired to prevent rupture, damage to frontal cortex often occurs. As a result, patients with anterior communicating artery aneurysms often exhibit memory impairments with hallmark features of dysexecutive amnesia, including impaired recall with normal recognition (Hanley et al., 1994; but see Delbecq-Derouesné et al., 1990), increased false alarm rates (Parkin et al., 1996), perseveration (Stenhouse et al., 1991), and confabulation. See Parkin and Leng (1993) for a review of frontal deficits associated with rupture of the anterior communicating artery.

Schizophrenic Memory Impairment

Although memory impairments are not the defining characteristics of schizophrenia, schizophrenics can have impaired memory. Notably, some of the memory disturbances observed in schizophrenic patients resemble those associated with dysexecutive amnesia. In particular, schizophrenics have a disproportionate impairment in recall compared to recognition (e.g., Goldberg et al., 1989). Moreover, schizophrenics show deficits on executive tasks that involve a prefrontal component. These memory and executive impairments mirror those observed in patients with frontal lesions, implicating the potential malfunctioning of the prefrontal cortex in individuals with schizophrenia.

Conclusion

From the above evidence, it is clear that the frontal lobes play an important role in strategic encoding, retrieval, and monitoring of memory. Damage to the frontal lobes, thus, often results in a wide array of memory disturbances, which are characterized here as symptoms of dysexecutive amnesia. To reiterate, prominent deficits of dysexecutive amnesia include

a disproportionate impairment in recall compared to recognition memory, difficulty with temporal ordering, source amnesia, perseveration, confabulation, and dysfunctional metamemory. Additionally, patients with frontal damage tend to have impaired working memory, heightened susceptibility to proactive interference, impaired frequency judgments, and high false alarm rates. Dysexecutive amnesia is a heterogeneous disorder because the types of symptoms that manifest in each patient depend heavily on the severity and origin of that patient's damage. Nevertheless, it is important to recognize the types of memory disturbances that result from frontal damage and to acknowledge that these types of memory problems are distinct from the memory deficits commonly observed in patients with medial temporal lobe damage.

Dysexecutive Syndromes

Abstract

The frontal lobes have a central role in cognition, emotion, and action related to their late evolutionary development and anatomical connectivity. However, damage to a wide range of brain regions can also produce these 'frontal deficits.' Thus, the term dysexecutive syndrome has clinical utility to capture a range of behavioral and cognitive deficits that can result from various diffuse neurologic conditions. This article will provide an overview of dysexecutive syndromes common in neurologic disease typically identified by neuropsychological and behavioral measures, with recognition that assessments have their limitations since dysexecutive deficits can be more pronounced under specific environmental circumstances.

Introduction

Establishing and maintaining goals over time is a critical requirement to gain mastery over the environment, and is optimized by the ability to monitor internal and external cues, and to maintain new information online to assist in generating alternate plans to changing contingencies. Adaptation to the environment is critical to maximizing the likelihood of goal attainment, and demands temporal control of initiation and suppression of behavioral responses. Ultimately, this requires orchestration and flexibility in controlling a diverse range of cognitive functions including planning, initiation, decision-making, inhibition, and set-shifting (for review see Damasio and Anderson (2003), Kolb and Whishaw (2003), and Lezak et al. (2004)). Furthermore, behavioral disorders such as apathy, abulia, perseveration, unconcern, unawareness, and poor self-monitoring can be observed in patients without cognitive deficits, and have resulted in proposed separate criteria for cognitive versus behavioral dysexecutive syndromes (Godefroy et al., 2010). However, quite often there is interplay between cognitive and behavioral deficits that characterizes the dysexecutive syndrome. For example, a failure to initiate an action can be classified as several intentional disorders, although intentional activity can clearly be influenced by emotional factors (motivation) or absence of initiative (apathy, abulia), demonstrating the interaction between behavior and cognition (Mesulam, 2000; Heilman et al., 2003). Conversely, initiation of behaviors can be inappropriate related to failures of response inhibition and can interfere with goal attainment, or become disruptive because of behavioral disinhibition, inappropriateness, increased talkativeness, lack of tact, and tendency to joke (Witzelsucht) (Adams et al., 1997). Therefore, there is a significant challenge in assessment and diagnostic characterization when considering the full range of cognitive and behavioral executive systems that can be differentially affected in neurologic disease.

Maintaining Executive Control

Conceptualization of executive functions can be described in terms of aspects of intentional activity that require initiation and organizational structure, with emphasis on the capacity to formulate a goal or intention and respond to changing contingencies.

Planning

Planning requires the ability to identify and organize the necessary steps to achieve a goal, the ability to conceptualize, view the environment in an objective fashion, generate alternatives, and make decisions prior to the initiation of a behavioral response (Lezak et al., 2004). There are few tests that directly measure planning, although standardized neuropsychological tests can yield insights into the organizational approach to a task, and the sequential ordering of actions to achieve a goal such as the Tower of Hanoi or Tower of London (Damasio and Anderson, 2003). Damage to the dorsolateral prefrontal cortex (PFC) has been associated with impairments in planning, although orbitofrontal cortex (OFC) damage is a better predictor of real-world planning deficits that require coordination of both cognitive and behavioral regulatory systems (Sarazin et al., 1998; Royall et al., 2002; Koechlin et al., 2000).

Initiation

The initiation and self-generation of behavioral responses over a period of time in order to accomplish a goal is mediated by bilateral superior medial frontal regions. The same segments of the frontal lobes result in reduced reaction times on tests of sustained attention, but appear to also involve supplementary motor area (SMA) and pre-SMA (Stuss et al., 2005). Slowed responding and decreased initiation can occur across a number of cognitive and behavioral domains resulting in devastating functional consequences. Tests measuring generational capacity (e.g., verbal fluency) under time and rule constraints are frequently utilized in neuropsychological assessment, although deficiencies are not always secondary to executive dyscontrol given the speech and language demands (Lezak et al., 2004; Kolb and Whishaw, 2003; Stuss et al., 1998; Stuss and Alexander, 2007). Nonetheless, speech and language output also require movement selection mediated by frontal speech zones, and during a fluency task words are responses

generated in the context of both internal and external stimuli (Passingham, 1993). Similarly, the generation of complex sequential movements involves the SMA, in particular, when relying on internally driven self-paced movements (Passingham, 1993; Deiber et al., 1991). Alexander Luria introduced motor sequencing tasks (fist-edge-palm) into neuropsychological assessments and this continues to be a classic test for the integrity of the frontal lobes (Luria, 1966).

Inhibition

Failure to inhibit behavioral responses that are mismatched to environmental circumstances are hallmark features of frontal lobe disease, and can become most apparent when patients exhibit inappropriate verbal or behavioral responses (Lezak et al., 2004; Mesulam, 2000). This type of behavioral disinhibition can have significant consequences on real-world functioning in terms of interpersonal relationships, as well as consequences of impulsive or faulty decision-making. Lesions in the OFC and medial frontal areas (i.e., parts of the frontal lobe containing paralimbic cortex) have been closely implicated in behavioral disinhibition and poor emotional regulation (for review see Damasio and Anderson (2003), LeDoux (1996), and Mesulam (2000)). Assessment of behavioral dysregulation (e.g., apathy and disinhibition) has been conducted utilizing behavioral rating scales such as the Frontal Systems Behavior Scale (FrSBe) (Paulsen et al., 1996). Since behavioral apathy is predictive of impaired activities of daily living, behavioral scales may provide additional predictive functional information above that available from cognitive tests (Norton et al., 2001; Stout et al., 2003).

The frontal lobes have been implicated in failure to withhold responses, with the PFC specifically controlling the timing of when to initiate and when to withhold a response (Lezak et al., 2004). A number of cognitive tests have been utilized to measure response inhibition including the Stroop test, Trails B, Digit Span Backwards, and Go–Nogo paradigms (see Lezak et al. (2004) for review and description). Trails B and Digit Span Backwards have loaded with the Stroop on a single factor of response inhibition, although other investigators have emphasized aspects of mental control in contrast to inhibitory control (for review see Royall et al. (2002)). Evidence from fMRI supports anterior cingulate and mesiofrontal extensions mediating Stroop processing reflecting that it taps into multiple dimensions of executive control simultaneously (Royall et al., 2002; Peterson et al., 1999). Impairment on the Go–Nogo task has been associated with PFC lesions in both animals and humans (Drewe, 1975; Royall et al., 2002), and recently with lesions to the superior medial frontal region (including the SMA) (Picton et al., 2007).

Cognitive Flexibility

Failure to alter behavior in response to environmental demands can stem from both faulty decision-making, as well as poor transfer of learning from past consequences so that it efficiently influences current behavior (Damasio and Anderson, 2003; Bechara et al., 1999). The OFC has been implicated in the decision-making process, and damage to this region can impair estimations of the strength of the reward associated with an outcome, resulting in devastating consequences on functional outcomes (Wallis, 2007). Because of the extensive connections with the limbic system, cingulate and hippocampus, the OFC influences emotionally driven decision-making, with uncertainties reconciled with decisions based also on past memory of reward and punishment (Carmichael and Price, 1995). However, comparison of patients with amygdala and ventromedial PFC lesions, suggests that while the OFC has primary role in decision-making, the amygdala mediates attachment of affective attributes to stimuli (Bechara et al., 1999).

Classic neuropsychological measures of executive functioning have concentrated on measuring how rapidly individuals modify well-learned behaviors in response to changing environmental cues. The two most common tasks utilized are the Go–Nogo task (also measuring response inhibition) and the Wisconsin Card Sorting Task (WCST). There has been considerable research on the WCST suggesting that frontal lobe lesion patients (in particular PFC lesions) are more severely impaired in their ability to shift response sets from previously learned criteria to new feedback provided by the examiner (Berg, 1948; Grant and Berg, 1948). However, the WCST measures multiple dimensions of executive control and performance does not appear to be specific to frontal lobe damage but can involve widespread brain regions (Royall et al., 2002; Stuss et al., 2000).

Ecological Validity of Assessment

Although specific neurologic conditions may have expected prominent dysexecutive syndromes (e.g., traumatic brain injury, Parkinson's disease, and Frontotemporal dementias), cognitive and behavioral dysexecutive syndromes can be present in a wide range of neurologic conditions given the dense connections between the frontal lobes and other regions of the brain. The traditional tests of frontal-executive dysfunction reviewed above are outlined with respect to aspects of executive control typically evaluated in a traditional neuropsychological assessment. However, standardized tests may be remote from and not informative about functional failures in real life and whether patients are able to meet goals and reintegrate in a psychosocial fashion following neurologic disease. Thus, there is a need for improved ecological assessment of executive functions, which could ultimately predict treatment outcomes and everyday functioning (Burgess et al., 2000).

Abstract

Children with developmental dyslexia have specific problems with reading and spelling. These problems have no apparent environmental or neurological cause, and are thought to be due to difficulties in the accurate specification and neural representation of the sound structure of speech. The normal development of lexical representation across languages is outlined, followed by a survey of the abnormal lexical development characteristic of developmental dyslexia. Possible basic auditory processing deficits are considered. Relevant information from brain imaging and genetic linkage studies is then discussed. Finally, possible subtypes of developmental dyslexia, and the usefulness of a discrepancy definition, are discussed.

Developmental dyslexia can be characterized as a specific problem with reading and spelling that cannot be accounted for by low intelligence, poor educational opportunities, or obvious sensory or neurological damage. Children with developmental dyslexia often appear to have good spoken language skills and extensive vocabularies. Accordingly, the first theories of developmental dyslexia postulated underlying deficits in visual processing ('word blindness'). Recent evidence from developmental psychology, genetics, and brain imaging suggests, however, that the central deficit in developmental dyslexia is a linguistic one. In particular, dyslexic children appear to have difficulties in the accurate specification of phonology when storing lexical representations of speech.

The Normal Development of Lexical Representations

A schematic view of a lexical representation is shown in Figure 1, illustrating different levels of phonology. Research in child phonology suggests that, prior to acquiring literacy, the child has represented spoken words as distinctive but complex auditory patterns ("prosodic templates," Vihman and Croft, 2007). These prosodic patterns vary in terms of auditory parameters like loudness, pitch, and duration. When the children learn to read an alphabetic language, they learn that these complex auditory patterns can be represented by sequences of letters. This changes the way in which spoken words are represented in the brain. Phonology is 'remapped' to reflect letter-sound knowledge (Frith, 1998). Frith (1998) wrote that acquiring the alphabetic code was like catching a virus: "This virus infects all speech processing, as now whole word sounds are automatically broken up into sound constituents. Language is never the same again" (p. 1051).

Figure 1 Schematic depiction of a lexical representation, showing different linguistic levels of phonological representation and example tasks.

Prior to learning to read, the phonological representation of lexical forms is relatively holistic, based more on prosodic characteristics and global phonological characteristics. For English, the dominant prosodic template is a rhythmic pattern comprising two syllables, with stronger stress on the first syllable. Examples are 'mummy,' 'daddy,' 'baby,' and 'bottle.' Mothers and fathers across languages use a special prosodic register, called infant-directed speech (IDS), to highlight these rhythmic cues for their babies. IDS uses auditory features like exaggerated rhythm and intonation, heightened pitch, and increased duration. This prosodic exaggeration seems to serve a language learning function, helping infants in different languages to extract individual words on the basis of pitch and rhythmic cues (e.g., Echols, 1996). Speech rhythm is very important for lexical learning, and infants can distinguish languages belonging to different rhythm types from birth.

For individual lexical items (words), research with preliterate children shows that syllables are represented first (a word like *wigwam* has two syllables). Preliterate children also represent *onsets* and *rimes* (the onset in a syllable corresponds to the sound/s before the vowel, the rime corresponds to the vowel and any subsequent sounds, e.g., *p – it*; *scr – ew*). As children learn to read, children represent *phonemes*, and they do this very rapidly in transparent orthographies. Phonemes are the smallest units of sound that change word meaning (e.g., *pit* differs from *sit*, *pot*, and *pin* by the initial, medial, and final phonemes, respectively). However, phonemes are an abstraction from the actual speech stream. For example, in English, the sound symbolized by the letter P has one acoustic form in the spoken word 'cap,' and a different acoustic form in the spoken

 http://dx.doi.org/10.1016/B978-0-08-097086-8.54003-3

word 'spoon.' Beginning readers are aware of this and may try to write the word 'spoon' as SBN. To become efficient readers, they need to develop orthographic representations that supplement and on occasion rerepresent the early-developing acoustic representations of speech (their prosodic templates).

Children with dyslexia have ongoing difficulties in the representation of phonology, and these difficulties are at all phonological levels, including prosody. Much of the evidence for this 'phonological deficit' has come from word-level 'phonological awareness' tasks, in which children are asked to make judgments about shared phonology or to manipulate phonology (e.g., the *rhyme oddity* task, in which the child is asked to distinguish the odd word out from a triple like *man, pat, fan*, and the *phoneme substitution* task, in which the child is asked to substitute the initial phonemes in words, so that Bob Dylan becomes Dob Bylan). A large number of studies carried out in many languages have shown that dyslexic children perform poorly in these sublexical phonological awareness tasks, and also in syllable awareness tasks (see Ziegler and Goswami, 2005; for a cross-language review). Importantly, such deficits are found even when dyslexic children's performance is compared to that of younger children who are reading and spelling at the same level as them (the methodologically important *reading level match* research design, which holds reading level constant rather than chronological age and thus gives a mental age advantage to the dyslexic children). More recently, it has been shown that children with dyslexia also have prosodic difficulties, for example, finding it difficult to judge whether syllables are stressed or unstressed (Goswami, 2011). They also find it difficult to judge patterns of beat distribution in music, and these difficulties are also found in comparison to younger, reading level matched children (Goswami et al., 2013). A phonological deficit seems to characterize dyslexia across languages. This suggests that an important causal factor in dyslexia is an underlying difficulty in developing phonologically well-specified lexical representations of speech, at all phonological levels (see **Figure 1**).

The Abnormal Development of Phonological Representations in Dyslexia

The cognitive profiles of developmental dyslexics show fairly specific linguistic deficits that are related to phonology rather than semantics. For example, developmental dyslexics have poor phonological memory skills, finding it difficult to remember verbal sequences. Developmental dyslexics are also slower to recognize familiar words on the basis of acoustic input. For example, they require more acoustic phonetic information than age-matched controls to recognize familiar words in speech gating tasks, in which incremental segments of speech from word onset are presented through headphones. They also find it more difficult to judge 'DeeDee' sequences, in which a familiar phrase or name is represented using the stressed syllable DEE and the unstressed syllable 'dee,' so that 'Harry Potter' would be DEEdeeDEEdee. Children with dyslexia also show problems in confrontation naming tasks (in which simple pictures must be named on demand), even though they are very familiar with the items in the pictures. Developmental dyslexics find rapid 'automatized' naming (RAN) tasks difficult. These tasks require the child to name familiar items presented in lists (such as digits) as quickly as possible, thereby accessing and outputting what should be well-practiced and so well-specified phonological forms ('nine, two, five,…'). RAN tasks are particularly strongly associated with dyslexia in transparent alphabetic orthographies, and in nonalphabetic orthographies, like Chinese (Ho et al., 2002). In both transparent alphabetic orthographies and nonalphabetic orthographies, children with dyslexia can learn to recode symbols to sound very accurately. Nevertheless, they never become fluent nor automatic readers, continuing to struggle with the fluent recoding of visual symbols into sound.

Auditory Processing Problems

Studies that have attempted to uncover basic auditory processing deficits at the phonetic level to explain dyslexic difficulty in representing phonological forms have so far produced mixed results. For example, some dyslexic children have great difficulty with 'minimal pairs' tasks that require the discrimination of similar sounding words (e.g., *smack–snack*), yet others do not (Adlard and Hazan, 1998). Some dyslexic children find phoneme categorization and repetition tasks very difficult (e.g., discriminating between or repeating /b/and /d/), and others do not (e.g., Manis et al., 1997). More recently, basic auditory processing tasks that are relevant to the recovery of prosodic structure from the speech stream have been developed, and these measures have shown more consistency across studies and also across languages. A review of auditory sensory processing in dyslexia (Hämäläinen et al., 2013) identified amplitude envelope rise time and duration as auditory measures showing the largest average sample size weighted effect sizes (0.8 for rise time, 0.9 for duration). The whole band amplitude envelope of speech is the fluctuations in the summed energy (intensity) of the signal across different frequency bands, and rises in intensity in this sound envelope (rise times) correspond to syllable onsets. Accurate perception of the amplitude envelope contributes to speech rhythm. Differences between dyslexics and controls in amplitude envelope rise time measures were found in all the studies reviewed by Hämäläinen et al. (2013), and individual differences in rise time sensitivity were linked to reading/spelling in all the studies. Therefore, at least some of the phonological difficulties found in dyslexia appear to be related to auditory processing difficulties (Goswami, 2011).

Phonological Processing Deficits in Dyslexia: Brain Imaging Studies

Brain imaging studies provide converging evidence that the key difficulty in dyslexia is a weakness in the representation of phonological information. The phonological processing system spans a number of cortical and subcortical regions in the brain, including frontal, temporal, and parietal cortex. Word recognition in skilled readers appears to depend on a left-lateralized network of frontal, temporoparietal, and occipito-temporal regions (Price and McCrory, 2008). Interpretation of functional neuroimaging studies of dyslexia is complicated

by the fact that most studies involve adult developmental dyslexics, which means that the brain's compensatory developmental trajectories will account for some if not all of the differences in patterns of task-related activity that are found. Nevertheless, available studies converge in showing underactivation of the key frontal, temporoparietal, and occipitotemporal structures in dyslexia (Pugh, 2006; for review). While all these studies rely on blood flow measures (PET or fMRI), studies focused on mechanism and relying on EEG or MEG are also appearing in the literature. One promising new direction is the study of oscillatory processes in the dyslexic brain. Amplitude (intensity) modulations in different frequency bands in the speech signal appear to be encoded, at least in part, by oscillating networks of auditory neurons that align their endogenous temporal fluctuations with intensity fluctuations in the input. Both syllable rate (delta, 0.5–4 Hz) and phonetic rate (low gamma, ~30 Hz) oscillatory processes have been shown to be atypical in adults with dyslexia (Lehongre et al., 2011; Hämäläinen et al., 2012).

Genetics of Developmental Dyslexia

The heritability of dyslexia has been demonstrated by a large number of studies that have identified multiple genes, as well as multiple environmental risk factors (Peterson and Pennington, 2012; for review). Studies are converging on six candidate genes and moderate heritability effects, with important gene by environment interactions (e.g., the genetic contribution to dyslexia is higher in families with high parental education levels). Most genes identified so far participate in neuronal migration and axon guidance, hence have not thrown further light on causation, and a genome-wide association study of dyslexia remains to be carried out. Genetic studies to date have depended on definitions of the dyslexic phenotype that are based on deficits in phonological awareness tasks and single or nonsense word reading. Thus there is evidence that individual differences in phonological processing are to some extent heritable. Of course, there cannot be a 'gene' for dyslexia in the sense that there is a gene for eye color, as reading is a culturally determined activity. The finding that the genetic contribution to dyslexia actually increases for children who develop in a favorable early environment as far as reading is concerned (children who have carers who stimulate their linguistic awareness via language games, nursery rhymes, and so on, and who read books to them and model and encourage literacy activities by reading and writing extensively themselves) nevertheless suggests that genes are important.

Subtypes of Developmental Dyslexia and the Discrepancy Definition

Historically, there was some debate over whether there were two subtypes of developmental dyslexia: 'surface' dyslexia and 'phonological' dyslexia. Phonological dyslexics were thought to have problems in assembling sublexical phonology (reading using abstract spelling-to-sound 'rules') and this is the phenotype that has been discussed here. Surface dyslexics were thought to have problems in using stored lexical knowledge to pronounce words (they seemed to have difficulty in addressing orthographic representations directly). This 'double dissociation' model of developmental dyslexia was drawn from patterns of adult pathology (the 'acquired' dyslexias) and has been largely discounted. The subtyping argument depended critically on the use of regression procedures, in which performance relationships between the use of lexical and sublexical phonology characteristic of normal children were used to derive confidence limits for assessing the same performance relationships in dyslexic populations. These regression procedures typically depend on the use of *chronological* age-matched normal readers. As processing trade-offs between the reliance on lexical and sublexical phonology may depend on the overall level of word recognition that the child has attained, *reading level* matched controls are more appropriate. Stanovich et al. (1997) demonstrated clearly that when reading level matched controls were used to define processing trade-offs, then almost no 'surface dyslexic' children were found.

More recently, there has been debate over whether the term 'dyslexia' should apply only to children with reading and spelling problems who do not have low intelligence. Siegel and others have long argued that the use of IQ scores to identify dyslexia discriminates against people of different cultural, economic, and/or linguistic backgrounds, and prevents people who need remediation and accommodations for their dyslexia from obtaining the help that they need (Siegel, 1989). As both neuroimaging data and studies of basic auditory processing have identified very similar patterns for children with discrepancy-defined dyslexia and for low-IQ poor readers, in future it seems likely that dyslexia will be defined without recourse to IQ. Hence children who show poor reading and spelling in the absence of poor educational opportunities or obvious sensory or neurological damage, irrespective of IQ, will be identified as requiring additional educational support.

Toward a Phenotype of Dyslexia

Neurodevelopmental disorders are not discrete syndromes, but most typically have a graded character. They are also seldom highly specific, and rarely involve a single deficit. Although a difficulty in representing phonology appears to be the core symptom of developmental dyslexia, many researchers have noted a number of associated deficits that more or less frequently accompany the phonological deficit. For example, dyslexic children can be clumsy, they can have attentional problems, they may have subtle abnormalities in visual processing (such as poor motion processing when visual stimuli are of low contrast and low luminance), and they can have atypical visual–spatial attention. Nevertheless, at present the most widely accepted phenotype of developmental dyslexia depends on deficits in performance on a battery of cognitive tasks that tap the integrity of the child's phonological representations of speech. This battery most typically includes phonological awareness tasks, single word and nonsense word reading tasks, letter knowledge tasks, and RAN tasks. Developmental dyslexia is thus currently best conceived as a subtle linguistic deficit that involves an impairment in the representation of the phonological structure of the speech signal in the brain.

Abstract

Acquired disorders of reading and writing in previously competent readers and writers following damage to the brain are known as *alexia* and *agraphia*, respectively. This article reviews the symptom presentation and underlying mechanisms of various forms of these disorders. A brief discussion on reading and writing disorders in scripts other than English and testing theoretical models via computational modeling concludes the article.

The term alexia refers to a disorder of reading, and is generally used to describe an acquired reading impairment in a previously competent reader, resulting from damage to the brain. This is contrasted with the term dyslexia, which has been used to describe both acquired and developmental reading disorders. Agraphia (also referred to as dysgraphia) is an acquired writing disorder in a previously competent writer, typically resulting from damage to the brain. Different forms of alexia and agraphia disrupt the complex processes of reading and writing in different ways. Observing the various forms of these disruptions can inform our understanding of how language is processed. Forms of alexia and agraphia are often classified according to the pattern of errors they entail.

Forms of Alexia

Central alexias are reading disorders that occur in the context of disruptions to the entire language system and typically accompany other impairments, such as auditory processing difficulties, anomia, aphasia, and/or agraphia. Two distinct reading routes can be relatively impaired in central alexia: reading by sound and reading by sight (Leff, 2004).

Phonological alexia (reading by sight) refers to cases in which the ability to read nonwords aloud is selectively impaired relative to the ability to read real words aloud, as first reported by Beauvois and Derouesné (1979). Ability to read both regular and irregular real words can be nearly intact, with patients reading 85–95% of real words correctly, while even simple nonwords but pronounceable letter strings are unreadable. Patients may also make visual errors in reading and show imageability effects (more concrete words, 'flower,' are more easily read than abstract ones – 'hope').

According to the dual-route model of reading, this form of alexia results from the impairment of the ability to convert graphemes (the smallest units of written language; symbols representing a single sound) to phonemes (the smallest units of spoken language; a single sound). Because patients cannot use the phonological (spelling-to-sound) route for reading, they rely on prior exposure to word forms, and fail to read novel words and nonwords, even those that follow 'legal' pronunciation rules.

Phonological alexia is associated with left perisylvian lesions. Phonological alexia has also been observed to occur in patients with right parietal lesions, who may make more positional errors than alexic patients with left-hemisphere lesions make (Buiatti et al., 2012). A computational modeling study has suggested that phonological alexia may arise from *non*phonological impairments. Nickels et al. (2008) produced impairments matching two symptomatically distinct patients by lesioning the nonlexical route of a dual-route model, implying that phonological alexia may stem from multiple levels of impairment and that no single lesion site can explain all real-world symptom patterns.

Patients with *deep alexia* may read fluently, but make semantic errors such that their produced word is related to the target in meaning but not its graphemic or phonological form (Marshall and Newcombe, 1973). The word 'hound' may be read as 'dog,' the word 'wood' as 'tree.' Patients with deep alexia are usually unable to read nonwords, but produce irregular words with the same semantic errors as regular words. Part of speech effects have been observed, such that nouns are read with fewer errors than verbs and function words. Imageability effects similar to those in phonological alexia are present. Visual errors (*angle* → *angel*) and morphological errors (*running* → *runner*) are also made. The only striking difference in symptom patterns between phonological and deep alexia is the presence of semantic errors in the latter, leading to the suggestion that the two are at opposite ends of a continuum, with phonological being a mild form and deep a severe form of the same impairment (Glosser and Friedman, 1990). Deep alexia is associated with extensive damage to the left temporo-parietal lobe (Leff, 2004).

Case studies and functional imaging studies have found support for a right hemisphere explanation of deep alexia, which suggests that reading errors are produced when the intact reading mechanisms in the right hemisphere are used in place of the extensively damaged normal reading system (Coltheart, 2001). This is opposed by the multiple-deficit hypothesis, which suggests that errors result from the multiply damaged normal reading system in the left hemisphere, following the same damage model as theories of other central alexias.

Several competing explanations of the semantic errors produced in deep alexia are proposed, and although many have gathered empirical support, none adequately address all the evidence. The typicality effect (faster processing for typical semantic category members than atypical ones; e.g., *robin* is

a more quickly processed member of the bird category than *ostrich*) has been used to test for semantic processing impairments in deep alexia. Findings indicated that patients with deep alexia process written, visual, and auditory semantic information differently than both normal and phonologically alexic patients, suggesting an underlying semantic processing impairment (Riley and Thompson, 2010). Another explanation of deep alexia is the modified failure of inhibition theory that proposes that semantic errors are caused by a failure to inhibit incorrect responses at the level of initial semantic processing (Riley and Thompson, 2010).

Surface alexia (reading by sound) describes the reversal of the pattern seen in phonological alexia: it is characterized by worse reading of real words than nonwords. Patients with surface alexia appear to over rely on the standard relationships between letter groups and their corresponding pronunciations, therefore being able to correctly pronounce nonwords by applying regular spelling-to-sound rules but being unable to pronounce irregular words (words in which spelling–sound relationships violate standard phonological rules).

Patients with surface alexia make frequent 'regularization errors,' in which they pronounce irregular words according to regular pronunciation rules. Other difficulties that occur include a length effect (regular and nonwords with more graphemes lead to more errors than those with fewer graphemes) and a frequency sensitivity (performance is worse for low-frequency irregular words than high-frequency ones). Some patients have also been observed to produce an 'irregularization error' with regular words (Patterson et al., 1996). A strong frequency–regularity interaction has been found, in which there is especially poor reading of low-frequency words with irregular spellings (Welbourne et al., 2011). Surface alexia is often observed following parietal or temporoparietal strokes, as well as in patients with progressive semantic dementia (Roeltgen and Lacey, 2010).

A distinction is made between 'output' and 'input' surface alexia. In the 'output' form, errors are not the result of impaired visual word recognition, but of the failure to retrieve word-specific pronunciation information. This retrieval failure leads the patient to use the procedure for reading nonwords aloud: 'sounding out' a word based on regular spelling-to-sound rules, which leads the patient to make regularization errors while reading aloud (Coltheart, 2001). The 'input' form of surface alexia is the failure to recognize a written word as an orthographic whole, therefore requiring translation of the word into phonology by applying standard spelling-to-sound rules. Then, regularization errors lead to the retrieval of the wrong semantic definition, as in the case of patient CD, who defined the irregular printed word *bear* as "a drink, beer" (Coltheart, 2001).

In *lexical nonsemantic reading*, patients lose the ability to comprehend written words, spoken words, and printed pictures, due to the loss of knowledge of word meanings. Schwartz et al. (1980), Cipolotti and Warrington (1995), Coslett (1991), and Lambon Ralph et al. (1995) each document cases of patients with severe semantic impairment but good irregular-word reading, providing evidence for a model of reading with a meaning pathway that is independent from the orthography–phonology (spelling-to-sound) pathway. Although this form of alexia can result from head injuries, it most commonly occurs as a result of progressive brain deterioration, such as in Alzheimer's disease (Coltheart, 2001).

Peripheral alexias are a category of isolated reading impairments that are not accompanied by impairments in other language processes. Generally, these disorders are caused by disruptions in prelexical visual processes, including visual field disorders, visual acuity deficits, and disorders of visuospatial perception.

Pure alexia, the oldest and best-known peripheral reading disorder, is characterized by an inability to read words and nonwords while all other language processes remain intact. Patients are able to recognize and name individual letters, but are unable to efficiently read single words or sentences. Some patients have difficulty distinguishing visually similar letters (Fiset et al., 2006), and some have shown difficulties processing numbers and nonlinguistic stimuli (Starrfelt et al., 2009; Roberts et al., 2010).

Patients with pure alexia can often pronounce words correctly using a backward spelling strategy, in which they dissemble a word into its constituent letters, identify each letter, and then reassemble the letters sequentially. This slow, laborious process is called *letter-by-letter reading*, and shows a linear increase in reading time with word length. The word-length effect has been found to be widely variable across patients, ranging from 97 to 2402 ms per letter (Pflugshaupt et al., 2009). Meanwhile, some patients read too quickly to be relying on letter-by-letter reading at all.

It has been observed that patients with pure alexia often read numbers with more speed and accuracy than alphabetic characters, a finding initially taken as evidence of a separate visual processing system for letter and number recognition. A recent literature review (Starrfelt and Behrmann, 2011) found little support for a dissociation between intact number reading and impaired letter recognition, and noted that normal readers are also better at identifying numbers than letters in brief exposure tasks.

The phenomenon of implicit recognition (also called covert reading) has been observed in many patients with pure alexia. When letter strings are presented for too short a time for explicit recognition to occur, some patients are able to perform semantic classification and lexical decision tasks with an accuracy well above chance. Accuracy on lexical decision-making has been found to be related to the frequency and imageability of the words, and inversely related to severity of injury (Roberts et al., 2010). Saffran and Coslett (1998) argue that the intact right hemisphere enables word recognition but not pronunciation, whereas the left hemisphere operates on information transferred from the right to produce letter-by-letter reading. A competing account is that implicit recognition reflects partial activation in the damaged standard reading system (Lambon Ralph et al., 2004).

Several theories about the mechanism underlying pure alexia have been proposed, including damage to the principal components of the reading system, such as letter identification, that prevents the normal parallel processing that enables rapid, accurate word reading (Saffran and Coslett, 1998); a general perceptual deficit that is especially pronounced with orthographic stimuli, which place high demands on the visual system (Starrfelt et al., 2010); impaired encoding and processing on a prelexical level; and deficits in the system by which

whole word forms are accessed. A connectionist neural network model that accounts for the stage of letter processing was able to simulate letter-by-letter reading, letter confusability, and error patterns matching data collected from patients with pure alexia (Chang et al., 2012). This model predicted patient reaction time above and beyond word length, providing evidence for a visual deficit account of pure alexia.

Functional imaging studies and case studies have proposed a causal link between pure alexia and lesions in an area of the brain linked to visual word forms (Pflugshaupt et al., 2009). The disorder is also associated with lesions to the left occipito-temporal region and the splenium of the corpus callosum. More than 90% of patients with pure alexia also have right hemianopia and visual field deficits, conditions known to negatively impact reading speed (Leff et al., 2006). Rare case examples of pure alexic patients without visual field deficits provide support for the assumption that symptoms of pure alexia are unrelated to the comorbid hemianopia, although many patients with pure alexia may suffer from hemianopic alexia as well (Johnson and Rayner, 2007). Sheldon et al. (2012) found that patients with both pure alexia and hemianopia had significantly larger word-length effects than patients with pure alexia and no hemianopia, suggesting that hemianopia may compound the impairments present in pure alexia.

Severe cases of pure alexia are known as *global alexia*, a condition characterized by very slow and inaccurate letter naming, and sometimes an inability to recognize letters at all. Often, patients with global alexia are still able to write and spell with normal or near-normal accuracy, and number recognition may be spared (Leff and Schofield, 2013). Patient VA (Volpato et al., 2012) exhibited severe reading deficits, including an inability to match spoken letters and numbers to their graphemic forms, but showed evidence for covert reading of single characters, including the ability to recognize shape, orientation, and case of letters. This pattern of impairments suggests preserved access to representation of letters and numbers as visual objects, and may be explained by right hemisphere reading.

Hemianopic alexia is the most common peripheral reading disorder. Patients with hemianopic alexia have intact language functioning, yet show severe reading impairments, including deficits in word identification and reading eye movements, such as smooth saccades and fixations. Hemianopic alexia is somewhat unique among reading disorders, in that lexical and post-lexical processes are fully functioning and impairments do not arise from damage to these systems. The hallmark symptom of hemianopic alexia is significantly reduced reading speed for text as well as for single words; reading accuracy is generally spared. There is also a linear increase in reading time for each additional letter (although less pronounced than the same effect in pure alexia). Reading errors are relatively rare in these patients, but consist of visual omissions of letters, syllables, and short words, and guessing errors, in which patients make meaningful completions of partially seen words (Schuett et al., 2008). Eye-tracking analyses of text reading show that patients with hemianopic alexia have longer fixation and gaze duration than normal readers (Spitzyna et al., 2007). This form of alexia is believed to result from damage to the primary visual cortex that leads to visual field loss (Leff and Schofield, 2013).

Visual alexia is defined by frequent visual errors, in which words are misread as words with shared letters but no other similarities (i.e., *words* → *worse* or *garden* → *anger*). Errors can include substitutions, reordering, omissions, and additions of letters of the target word. It is suggested that these errors stem from a deficit in the visual analysis system at the level of letter identification (Friedmann et al., 2012). Only seven individuals with the classification of acquired visual dyslexia have been reported in the literature to date, reflecting a dearth in research on this form of alexia.

In *neglect alexia*, patients consistently make errors on either the initial or final letters of a word. The most common pattern is one of omissions (*slight* → light) or substitutions (*summer* → hammer) on the left side of a written word. Patients usually start reading sentences from the middle of a word string and are unaware of their impairment. Reading fluency is the same for regular, irregular, and nonwords, and comprehension and production of language are unimpaired. Additionally, these patients may be able to read words correctly if they are presented vertically (De Bleser and Luzzatti, 2008).

This form of alexia is generally found in patients with a left unilateral neglect syndrome, meaning that they do not attend to their visual field, body, and extrapersonal space on the left side. The most common lesion site associated with neglect alexia is the right parietal lobe. Because it is associated with unilateral neglect, neglect alexia is not specifically a disorder of reading, but instead reflects a wide range of neglect-related impairments.

Patients with *attentional alexia* describe letter crowding and migration of letters, and sometimes blend elements of two words into one. Patients are generally poor at reading text and are unable to report the letters making up words they can read. Migration errors often reflect the relative positions of the letters in the words (*land mine* → *lane mind*), a phenomenon unaccounted for by spatial coding impairment explanations of attentional alexia. These patients often perform better when word stimuli are presented alone, instead of flanked by other words and letters (Warrington et al., 1993). In lexical decision tasks, patients are more likely to accept nonwords whose letters can migrate within the string to become a word, but are not sensitive to phonological similarities between words and nonwords (Shalev et al., 2008). Attentional alexia is usually associated with left parietal lobe damage.

Forms of Agraphia

Writing impairments are often classified by the specific disruptions in the writing system they reflect. Individual profiles of agraphia syndromes are found in a variety of patients, reflecting disruptions at different stages of the theoretical spelling system. Agraphia rarely occurs in insolation. Patients with agraphia predominantly have alexia as well, often mirroring the same impairments in writing as in speech. However, the relationship between alexia and agraphia is not always straightforward and is not well understood. Evidence from patients with both phonological alexia and agraphia suggests that a modality-independent deficit underlies both disorders, rather than damage to separate, dedicated cognitive systems for reading and spelling (Rapscak et al., 2009).

Differences in the manifestations of alexia and agraphia may reflect writing processes that are more vulnerable to even mild damage to a distributed network of language processing, and relatively more resilient reading processes. Although a shared-component model in which the same cognitive systems support both reading and spelling is appealing, the relationship between alexia and agraphia is not always straightforward. Cases of patients with mismatched alexias and agraphias complicate our understanding of the interplay between reading and writing disorders, such as patient RG, who presented with surface agraphia and phonological alexia (Beauvois and Derouesné, 1979); patient MK (Howard and Franklin, 1988), who presented with deep dysgraphia and surface alexia; and patient JC (Bub and Kertesz, 1982), who presented with deep dysgraphia and normal reading.

Central agraphias are a class of acquired writing disorders related to impairments in linguistic output, not motor output. In *lexical* or *surface agraphia*, patients make spelling errors for ambiguous and irregular words, while the spelling of regular words and nonwords is relatively intact. The errors made in lexical agraphia are usually phonologically plausible, and high-frequency words are written more accurately than low-frequency ones. This form of agraphia is believed to represent impairment at the level of graphemic output, reflecting damage to orthography. Patients are unable to retrieve orthographic information for some words, so they generate spellings by relying on the nonlexical route, producing phonologically plausible spellings. Errors are made in irregular and ambiguous words for which a 'sounding out' process is not sufficient to generate the correct spelling. Lexical agraphia is usually found in patients with lesions at the temporo-parieto-occipital junction, and is also common in patients with Alzheimer's and semantic dementia (Rapcsak and Beeson, 2002).

Phonological agraphia is a pattern of impairments in the spelling of unfamiliar words and nonwords, while familiar words remain comparatively intact, even those with irregular or ambiguous spellings. The spelling errors are usually phonologically implausible, but may be visually similar to the correct spelling. Some patients are unable to write even single letters when given sounds. Phonological agraphia is commonly associated with damage to the left perisylvian cortex, including Wernicke's area, the supramarginal gyrus, and Broca's area. Although this agraphia has been conceptualized as involving a specific deficit in converting phonemes to graphemes, or a disruption in the nonlexical spelling route, a large-scale investigation of phonological alexia and agraphia patients (Rapcsak et al., 2009) supported a model in which writing impairments are a manifestation of central, modality-independent damage to phonology, not the result of damage to dedicated spelling (or reading) cognitive systems. This finding is compatible with both connectionist and dual-route models of reading and spelling.

Like deep alexia, *deep agraphia* is characterized by frequent semantic errors, lacking any orthographic or phonological similarity to the target word (e.g., writing 'apple' instead of 'banana'). Patients with deep agraphia have marked difficulties spelling nonwords, make morphological errors, sometimes produce visually similar misspellings, and make functor substitution errors (e.g., *from* → *for*, *to* → *in*). Fragment errors also occur, more commonly toward the end of a word, involving the deletion of two or more letters. As in alexia, this condition is considered to be closely related to the phonological form, with the major distinction that semantic errors are present. Deep agraphia is typically found in patients with large left hemisphere lesions and extensive damage to the left perisylvian cortex, and is believed to represent damage to lexical-semantic and sublexical processes. One theory is that the pattern of errors seen in deep agraphia is the product of writing that originates from the right hemisphere (Rapcsak and Beeson, 2002). *Global agraphia* is an extension of the same damage, resulting in severe impairments in spelling all words.

Semantic agraphia refers to 'writing without meaning,' or a fundamental disconnect between semantics and spelling. Patients with semantic agraphia produce errors in spontaneous writing, but are usually able to write to dictation relatively well. Homophones are commonly misspelled in dictation, because the patient is unable to use the semantic context to select the correct spelling. The spelling of ambiguous words, irregular words, and nonwords is generally intact when patients do not know the semantic meaning. Patients with semantic agraphia typically have damage in brain regions that are associated with semantic processing, but not the area of the left perisylvian cortex associated with language.

Graphemic buffer agraphia is an impairment at the level of working memory, so that letters held in short-term memory are lost. Graphemic substitutions are frequently seen, such as substituting vowels for other vowels and consonants for other consonants. Since nonwords make higher demands of the graphemic buffer, they usually contain more errors.

Central agraphias can be conceptualized as a continuum, such that treatment aimed at specific disruptions in the dual-route model of writing can shift more severe agraphic impairments to less severe ones (Beeson et al., 2009). Intervention of deep agraphia might use a lexical approach, focused on retraining specific words, and following treatment gains the condition that would resemble the less severe phonological agraphia. A phonological intervention focused on retraining sound–letter relationships could shift the syndrome to a pattern of impairments more similar to surface agraphia, which could be treated by training interactive use of lexical and phonological knowledge, and eventually result in normal, unimpaired writing. An example of this theoretical continuum in action was observed in patient MM (Greenwald, 2004), whose global agraphia evolved to surface agraphia after experimental treatment targeted sublexical reading and sentence spelling.

Peripheral agraphias are a class of acquired writing disorders related to impairment in the physical production of letters, with the linguistic properties of words intact. *Allographic agraphia* is an impairment in selecting the correct letter shape, resulting in partial or complete interruption in writing the intended letter. It may result from failure to access specific letter shapes from memory, or an impairment of letter-specific graphic motor programs. Some patients may be better at uppercase characters than at lowercase or vice versa, and substitution errors for physically similar letter shapes are sometimes present.

Apraxic agraphia is characterized by impaired motor execution of letter strokes, not caused by sensorimotor, extrapyramidal, or cerebellar dysfunction. Patients with apraxic agraphia

usually hold the pen correctly, but normal writing motions are replaced by slow, effortful, and imprecise strokes, sometimes producing illegible handwriting. Other errors include omitting strokes, inserting unnecessary strokes, and spatial neglect (e.g., writing on only half the page). Oral and keyboard spelling remain intact. Some patients may produce single letters comparatively well (Zettin et al., 1995), and some patients may write numbers without impairment (Hodges, 1991). The variety of lesion sites associated with apraxic agraphia suggests that the motor programming of writing is distributed throughout the neural system, and may also include the cerebellum (De Smet et al., 2011).

Patients with *afferent agraphia* are unable to use sensory feedback to calibrate or control the fine motor execution of handwriting, presenting with duplications of letters, omissions of letters, and a perseverance effect for sequences of similar letters or strokes, such as writing 'bellll' for 'bell' or adding/omitting legs of an 'm.' Cursive handwriting is more severely affected. Patients may also have difficulty writing on a horizontal line or keeping appropriate spacing between words. Afferent agraphia is typically observed in patients with right parietal lobe damage. It can also be produced in normal individuals if kinesthetic feedback is interrupted.

Alexia and Agraphia in Other Scripts

To date, most research on acquired reading/writing disorders has focused on monolingual English speakers. Evidence from reading and writing disorders in other languages contribute to our understanding of a cognitive model of reading and writing processes.

The *orthographic depth hypothesis* theorizes that the process of oral reading should vary according to the level of transparency between letters and sounds. Orthographically transparent languages, such as Spanish or Italian, have regular and predictable pronunciations based on the orthography of words, indicating that relying on a sublexical orthographic–phonological reading mechanism would result in the correct pronunciation for almost any letter string. Orthographically opaque languages, such as French or English, have variable and irregular relationships between letters and sounds, necessitating a lexical–semantic reading mechanism to determine correct pronunciation. Following the orthographic depth hypothesis, semantic reading errors (reading *symphony* → *orchestra*) and regularization spelling errors (spelling *yacht* → *yot*) should not be observed in languages with transparent orthographies. However, convincing evidence of this hypothesis in its strong form has not been reported.

The sublexical reading pathway is selectively damaged in phonological and deep alexia, and these patterns of impairments have been found in opaque orthographies as well as in transparent ones, including Greek, Welsh, Slovak, and Japanese kana (Hricová and Weekes, 2012). The lexical reading pathway is selectively damaged in surface alexia, which has also been observed in transparent orthographies such as Italian and German. These patterns of impairments suggest that a dual-route model of reading exists even in languages with transparent orthographies. One interpretation is that semantic errors in transparent scripts may arise only following severe damage to the sublexical mechanisms, while in opaque scripts such as in English, these errors arise following even mild damage (Hricová and Weekes, 2012). In Russian, a relatively transparent script, agraphias are more commonly reported than alexias, perhaps because mappings from sound to print are less predictable and, therefore, more vulnerable to errors following damage than the reading system (Kozintseva et al., 2012).

A dual-route model of spelling can explain agraphia in many scripts, including differential performance for different languages in bilingual speakers and differential impact of brain lesions on the reading of logographic, syllabic, and alphabetic writing systems (Senaha and Parente, 2012). The *language independent hypothesis* predicts that bilingual patients with agraphia use a single spelling system for both languages, so that a similar pattern of impairments will result in both languages if that system is damaged. But case studies have not supported this hypothesis. Patient AA (Kambanaros and Weekes, 2013) was premorbidly fluent in both Greek, a stem-based language with a complex morphology, and English, a word-based language. AA showed similar patterns of errors in nonword spelling in both languages, but differential effects of grammatical word class for word spelling in each language. The authors posit that these differential errors resulted from damage to the lexical–semantic pathway, where morphological knowledge is stored. Grammatical category and morphosyntactic features are more prominent in stem-based languages, therefore grammatical knowledge had an impact on the orthographic retrieval of Greek nouns, showing evidence for spelling via language-specific processes. Evidence of word class dissociations in morphologically rich languages like Spanish and Italian also help reject the language-independent hypothesis. Although the same spelling system is used, impairment can be differential based on different morphological demands of different languages.

Testing Theoretical Models of Reading and Writing

Theoretical models of reading and writing can be tested using computational modeling, or executable computer programs that 'read aloud' following the information-processing procedures, a particular theory suggests. One way these models are tested is by damaging certain components of the model to simulate different patterns of alexia. The goal is to produce the same patterns of impairments using the model, as the behavioral data from real-world patients provide.

There are two main theoretical models of reading and writing. There is the symbolic *dual-route model*, consisting of two distinct pathways. Through the lexical route, a word's graphemes map onto a representation of its visual form in the orthographic lexicon, directly activating knowledge about its pronunciation in the phonological lexicon. Between the input and output lexicons, the semantic system stores knowledge about word meanings. The nonlexical route uses specific linguistic rules to convert each grapheme to its corresponding phoneme, which is the process used when 'sounding out' unfamiliar words or nonwords. The computational Dual Route Cascade (DRC) model has been able to account for many reading phenomena (see Coltheart, 2006b, for review), including surface alexia, phonological alexia, letter-by-letter

reading, and deep agraphia (Bormann et al., 2008). The existence of patients with each of the different routes selectively damaged or spared following brain injuries provides support for this model (Coltheart, 2006b).

A criticism of the dual-route model is that data is fitted to a theoretically derived a priori model, reducing its biological plausibility and validity (Seidenberg and Plaut, 2006). Despite this shortcoming, existing data currently favors the DRC model (Coltheart, 2006b).

The connectionist *triangle model* is driven by data instead of theory. In this model, recurrent connections are simultaneously activated between orthographic, semantic, and phonological units, and whatever information is available is used to produce output. For example, nonwords have no meaning units, so their pronunciation cannot be accessed using an orthographic–semantic pathway; they must be read using an orthographic–phonological pathway (Harm and Seidenberg, 2004). The Parallel Distributed Processing (PDP) computational model does not impose hard-wired a priori rules, increasing biological plausibility, but relies on algorithms that are unlikely to occur in nature (Seidenberg, 2006). PDP models have been able to simulate some forms of developmental dyslexia, acquired deep and phonological alexia, and letter-by-letter reading (Bormann et al., 2008; Chang et al., 2012; Welbourne et al., 2011).

A diverse array of acquired reading and writing impairments provide insight into cognitive models of language processing. Computational modeling and the study of language disorders in other scripts offer new horizons for the developing field of cognitive neuropsychology.

This article is a revision of the previous edition article by J. Bennett, volume 6, pp. 3934–3939, © 2001, Elsevier Ltd.

Abstract

The purpose of this article is to provide broad-brush insights into current developments in early childhood care and education (ECCE) across the various and diverse regions of our world. These developments have given rise to a wide range of concerns, ranging from pragmatic issues in service delivery, funding and core principles for service provision to scholarly debates around pedagogical approaches, and philosophical orientation in programming. They also present opportunities for innovation and renewal through greater responsiveness to sociocultural needs and priorities in programming. The article uses examples of programs currently being implemented across some of the world regions to highlight some of these issues and opportunities. The article begins by highlighting some of the important and significant developments that ECCE has seen during the early years of this twenty-first century. It then details some major recent developments for ECCE in the world regions, along with some of the key challenges for ECCE that have emerged in recent years, as highlighted in the Moscow Framework for Action and Cooperation. These are illustrated through the use of reference to ECCE initiatives from countries within the world regions that might not commonly be represented in dominant scholarly circles. The article concludes with a brief summary of issues raised and possible steps forward in achieving high-quality, equitable ECCE provision for children inhabiting the world regions.

> Many things can wait; the child cannot. Now is the time his bones are being formed, his mind is being developed. To him, we cannot say tomorrow; his name is today Gabriela Mistral, Latin American poet and Nobel Prize winner.

According to rough estimates, a quarter of the world's 7 billion-strong human population is made up of children. During the past few decades, empirical evidence (Heckman, 1999; Shonkoff, 2010) to support sentiments articulated by Gabriela Mistral regarding the formative impact of early childhood care and education (ECCE) has led to a widening spread of interest and investment in young children's well-being, care, and education. These developments mark a significant period in the histo ry of ECCE.

The goal of this article is to provide a brief overview of recent developments that have occurred as part of the recent focus on ECCE, with particular attention to some key contemporary issues affecting policy makers, practitioners, and scholars from across the world regions. The entry begins with context setting, drawing particular attention to dissonance between the evidence base commonly referred and contributed to by scholars of early childhood and the reality of everyday life for the vast majority of children across the world regions. Current areas of development in formalized ECCE that are common across the world regions are then summarized, with examples of programs in place across parts of the world at the time of this writing used to highlight some contemporary issues in ECCE. Of particular concern, evidenced across recent discussions in both scholarly literature and in wider forms of knowledge sharing, is the importance of acknowledging alternative approaches to provision that are sufficiently dynamic or fluid to adequately represent diverse programs and realities. The entry concludes by summarizing some recent recommendations and implications for the development of ECCE across the world regions into the second quarter of the twenty-first century.

ECCE in the Twenty-First Century – Context Setting

Terminology used to refer to the care, development, and education of young children varies across countries and contexts, in most cases as a reflection of particular stances on early childhood. For example, in sub-Saharan Africa, preference for the term early childhood development (ECD) reflects a view that early childhood provision should be centered solely on the child, rather than on any particular method of care or model of education. In response to a historical distinction between 'care' and 'education' in European American contexts that has often led to 'siloed' approaches to ECCE policy and practice (reflecting a general view that children are cared for until a point at which they are ready to be formally schooled), the United Nations Educational, Scientific and Cultural Organization (UNESCO) adopts the term ECCE, which connotes a more holistic, intersectoral approach to early childhood programming that attends to all aspects of health, care, and education of children from birth to the age of 8 years. The term ECCE is widely recognized across the world regions and, where it has not been formally adopted, it is acknowledged in relation to regional definitions, as in the case of sub-Saharan Africa.

In providing an overview of ECCE across the world regions, it is important to begin by drawing attention to certain peculiarities in the current global context of ECCE. In scholarly circles, most discussions of children's development, care, and education tend

to assume at least a basic level of service provision, centering on expanding evidence and/or considering how to improve existing care and education systems mostly in operation across European American contexts (see, for example, recent issues of *Early Childhood Research Quarterly*, a leading journal in the discipline). However, it is important to note that at a global level, the early experiences of and availability of supports for children differ vastly, even in the twenty-first century. Data provided by the United Nations Children's Fund provide stark reminders that many children around the world regions still lack access to basic survival needs: an estimated 8.8 million children continue to die before they celebrate their fifth birthday, more than 70 million children are still out of school, and millions more lack protection against violence, abuse, exploitation, discrimination, and neglect (UNICEF, January 2012). Although international literature on ECCE increasingly recognize social and cultural diversity, as well as basic survival needs among some populations of children (Engle et al., 2007), it is important to acknowledge the dissonance between conditions commonly reflected in scholarly circles and the daily reality of ECCE experiences for many children across the world regions.

It is important also in reviewing ECCE across the world regions in the twenty-first century, to acknowledge an extensive historical background of studies and discussions around children, their place in society, and the nature of their growth and development. From the Puritans to Rousseau and the Romantics in European contexts, to Confucius in Chinese contexts, beliefs about children and childhood have been expressed throughout millennia. According to Wu (1996), essays on child rearing were written by Confucian scholars throughout the first century BC and by the time of the Ming (1360–1600s) and Qing (1600–1900s) dynasties, parenting 'manuals' were widely read. The value of children has also long been acknowledged in Islamic texts, which emphasize responsible child-rearing (Hasna, 2003).

ECCE in the Twenty-First Century – Recent Developments and Global Concerns

Evidently, societies and communities have cared for and educated their children across millennia. Formalization of ECCE provision at the level of global conventions reflected in national policies, however, is a relatively new phenomenon. Indeed, policy focus on ECCE has increased with unprecedented rapidity during recent years, due in part to (1) near-universal ratification of the United Nations Convention on the Rights of the Child and (2) international frameworks for action agreed upon by United Nations (UN) member states, such as Education for All (EFA) and the Millennium Development Goals (MDGs). EFA, which consists of a series of goals designed to promote universalization of quality basic education, cites ECCE as a key contributor to economic and educational development:

> The preconditions for education quality, equity and efficiency are set in the early childhood years, making attention to early childhood care and development essential to the achievement of basic educational goals. (Article 1.3)

In European American contexts toward the end of last century, evidence of the positive impact of preschool programs such as the High-Scope Perry Preschool Program in the United States, particularly for overcoming the effects of poverty and social disadvantage (Barnett, 1998), led to a raft of studies that highlighted the economic sense in investing in ECCE (Heckman, 1999) and a proliferation of ECCE initiatives. At a global level, also of significance in fueling the expansion of ECCE programs in both the majority world and European American contexts, has been the work of Young (1996) and Shonkoff and Philips (2000), whose research has established strong evidence of links between quality early childhood interventions, neurological growth, and lifelong development. Such work has been cited across the world regions by organizations, such as United Nations Children's Fund (UNICEF) and UNESCO, in driving initiatives for early childhood program provision to improve living conditions for young children.

Spurred by a combination of published scientific evidence and international goal setting, during the 1990s and the early 2000s, ECCE attracted intense interest across the world's diverse regions. Following a period of subsequent expansion, in recent years, discussions and research in ECCE across the globe have turned toward understanding complexities and implications of program provision and development. Challenges and opportunities related to the range of contextual factors influencing policies and programming have given rise to a greater focus on providing high-quality care and education, rather than simply attending to quantitative goals.

In response to this heightened awareness of the need to 'take stock,' reaffirm, and plan for the future of ECCE across the world regions, UNESCO sponsored its first World Conference on Early Childhood Care and Education in 2010. The Conference brought together 50 government ministers from across the world regions, as well as scholars, practitioners, and other high-level policy makers/advocates. In preparation for the Conference, regional reports from Africa, Arab countries, Asia and the Pacific, Europe and North America, Latin America and the Caribbean, and Russia were produced. These reports are now published on the UNESCO website (http://www.unesco.org/new/en/world-conference-on-ecce/reports/). Outcomes of the Conference are also published on the UNESCO website in the Moscow Framework for Action and Cooperation, which lists a set of goals and principles for steps forward in provision of formalized ECCE across the world regions. These goals, agreed upon by ministers, heads of delegations, representatives of UN agencies, development cooperation agencies, civil society organizations, education agents, and early childhood care scholars, represent what is arguably the most representative and accessible synthesis of current developments and concerns in ECCE across the world regions. The goals are likely to influence developments in ECCE for the foreseeable future and are therefore summarized briefly as a starting point for broader discussion.

The Moscow Framework for Action and Cooperation: Goals for ECCE across the World Regions

The Moscow Framework for Action and Cooperation outlines the following key areas of concern/focus in global future ECCE plans: Legislation, Policies and Strategies; Access and Scaling Up;

Assessment, Research, Monitoring and Evaluation; Equity and Inclusion; Quality; Capacity Building and Partnerships. In terms of legislation, policies and strategies, a common concern across the world regions is that while ECCE policies exist in many countries, they are not always included in national development plans and therefore lack political commitment/funding. ECCE policies also tend to lack clear operational frameworks to support implementation and sustainability. Countries also share, as reflected in goals outlined by The Framework, concern about the need to ensure access to programs for all children, regardless of geographical location and/or ability. In many countries, access to ECCE programs is greater for children living in relatively prosperous areas, defeating the purpose of providing support for the most vulnerable.

As countries focus increasingly on quality in tandem with quantity and access, the need for developing assessment and monitoring approaches based on contextually appropriate research evidence has become an urgent one across the world regions. As the Moscow Framework for Action and Cooperation suggests, a current focus for many countries around the world regions is on working with practitioners, policy makers, researchers, and communities to ensure that ECCE programs are built around localized resources, strengths, and knowledge bases.

All the key areas noted in the Moscow Framework for Action and Cooperation and referred to above are, to varying degrees and by different means, universal in their relevance. They are also, notwithstanding the important role of sociocultural contexts in shaping their unique nature and influence on ECCE within and across each of the world regions, strongly interwoven. Across numerous countries around the world, from Australia to Zanzibar, there is a strong focus on building into ECCE policies the need for provision of programs for children that are equitable, of high quality, and best suit national and community needs and priorities. The next section provides specific examples of ECCE initiatives from Oceania, Asia, and Africa that highlight strategies through which programs are responding to these goals for ECCE. While each has a unique purpose, all illustrate contemporary issues related to complexities around identifying the unique, contextual considerations to be made in the process of formulating policies, providing access, building capacity in working with communities, and monitoring quality of provision. Perhaps most importantly, these examples provide some insight into the extent to which currently available international literature in ECCE are lacking in evidence to support necessary innovations in ECCE provision across the world regions.

ECCE in the Twenty-First Century: Snapshots from Vanuatu, the Philippines, and Djibouti

Quality in ECCE – Teacher Preparation in Vanuatu

Of particular current interest across a wide range of contexts is the issue of quality in ECCE, from both conceptual and pragmatic points of view. In line with EFA goals, universal provision of ECCE has been a focus of countries around the world for some time. However, attention to issues regarding quality has emerged recently, with increasing evidence that low-quality services may at best offer little in the way of positive outcomes for young children and, at worst, be detrimental (UNESCO, 2004). The 2005 EFA Global Monitoring Report on the 'Quality Imperative' signaled a new focus on process features, in addition to quantitative factors, in ECCE provision. This focus is most recently outlined in the Moscow Framework for Action and Cooperation.

Of all the potential contributors to 'quality' in ECCE programs designed to support early learning and development, teacher quality is widely acknowledged as having the greatest influence. Without the presence of committed, confident, and knowledgeable human resources, the most advanced physical facilities are unlikely to engage young children in meaningful learning experiences (Alexander, 2008). In line with cultural–contextual expectations regarding professionalism, ECCE teacher quality in European American contexts is widely associated with formalized teacher education and tertiary-level qualifications (Degotardi, 2010). Applied to resource-constrained environments, where tertiary-level education is still a privilege, the direct implication of this would be that high-quality ECCE programming and implementation across many contexts is a virtual impossibility.

The following example of teacher training in Vanuatu serves as a useful illustration of complexities around expansion of ECCE, in terms of dynamics that need to be factored into policy making, attempts to scale up programs, and capacity building. A small Pacific island rich in cultural and natural resources but less advantaged economically, Vanuatu has developed some noteworthy and innovative ECCE programs that serve as useful illustrations of the need for consideration and promotion of locally bound definitions of 'quality' in teacher preparation. Vanuatu's example of teacher training supports Alexander's (2008) position that including contextually appropriate indicators of process in the design and evaluation of teaching is critical to achieving a 'quality' education system that engages and retains teachers and children.

Although not supported significantly in terms of public funding, ECCE in Vanuatu benefits from a strong, committed team of practitioners working within the national preschool association, PSABV (Pri-skul Asosiesen Blong Vanuatu). As a result, Vanuatu has recently seen some important developments in ECCE, including the development of a draft ECCE curriculum and incorporation of ECCE in the national definition of basic education. Current initiatives reported to be undertaken by the government include the Vanuatu Education Strategy (2008–09); Vanuatu Education Roadmap (2010–16), which looks at access, quality, and management components; as well as the Vanuatu Early Childhood Education Policy, which was launched in 2010 (James, 2012).

Much of the formalized teacher preparation that is available for ECCE teachers in Vanuatu is offered by external agencies, in the form of a bachelor's degree in Early Childhood Education, for which teachers must obtain an international scholarship and travel to Fiji, or a Certificate III in Children's Services (Childcare/Preschool Stream) course offered by the Australia-Pacific Technical College. The Vanuatu Preschool Association also offers short-term, intensive training with support from the Ministry of Education in Vanuatu. Teachers graduating from this training are then employed in community-based ECCE centers that provide programs for children aged 4 and 5 years, the preprimary school years.

A brief description of the Preschool Association/Ministry of Education teacher training is provided below. The applicability

of this training, which provides little of the theoretical knowledge and engagement with scientific research commonly required of professional training, is nonetheless self-evident. Anecdotal evidence also suggests that the local ni-Vanuatu training model results in positive outcomes, with trained teachers more likely to use the vernacular in their teaching (a priority for Vanuatu), more likely to engage in child-centered activities, and more likely to involve parents and community in children's learning (UNICEF Pacific and USP, 2004). An added benefit of this training program is that it has led to a strong national network facilitating direct communication between the Ministry Director for ECCE and teachers working across both proximal and remote regions.

The training typically consists of a 5-week program (Guild and Tuivaga, cited in James, 2007) that is first delivered to 'key teachers' at national level. These key teachers then implement the same training program to ECCE teachers working across the provinces. Among the many benefits associated with this training program is the close network of teachers that has developed across Vanuatu as a result of the links made between key teachers, the national Preschool Association, the Ministry of Education, and 'local' teachers who are located at provincial and village level.

A major aspect of the 5-week training program involves learning about construction of preschool buildings and equipment using readily available natural resources. When the key teachers travel to the provinces to conduct training for local teachers, they are accompanied by a builder who will then assist the local teachers and local communities in building new preschool facilities, where necessary. Teachers also receive training on how to make use of local materials to construct learning materials for the classroom.

Teachers also learn how to make a collection of learning materials using natural resources (including natural dye for colors). Ongoing supervision is provided to teachers by both provincial-level and national ECCE practitioners, who make regular visits to preschools. As Jenny James (Early Childhood Education Director at the Ministry of Education) explains:

> One of the commonest complaints from ECCE teachers is the lack of resources for teaching. Such a complaint need not be heard again…(i)n the Pacific, where our surroundings are full of natural resources and our communities are caring, we can count ourselves very fortunate. Where children are in need, and teachers and communities have the skills and imagination to invent, there can be no truer saying than necessity is the mother of invention. (James, 2007: p. 122)

Hess et al. (2004) have outlined the complexities involved in connecting teacher training to quality teaching. Scholarly debates around the nature and length of preparation required for quality teaching continue, particularly in the field of ECCE (ref). Given the current expansion in formalized ECCE programs across the world regions and contemporary calls for greater attention to quality provision, Vanuatu's case highlights a degree of urgency in the need for conceptualizations of quality that combine universalized standards with consideration of unique sociocultural, political, and economic contextual circumstances (Box 1).

Box 1 Case Study – ECCE Teacher Preparation in Vanuatu Extracted from James, 2007. Resources for ECCE. In: Puamau, P., Pene, F. (Eds.), Early Childhood Care and Education in the Pacific. The Pride Project, Pacific Education Series No. 5. USP, Suva, Fiji.

Training in Vanuatu for most ECCE teachers typically consists of a 5-week training programme (Guild and Tuivaga, cited in James, 2007) that is first delivered to 'key teachers' at national level. The key teachers then implement the same training programme to ECCE teachers working across the provinces. Among the many benefits associated with this training programme is the close network of teachers that has developed across Vanuatu as a result of the links made between key teachers, the national preschool association, the Ministry of Education, and 'local' teachers who are located at provincial and village level.

Jenny James (Early Childhood Education (ECE) Director at the Ministry of Education) explains:

One of the commonest complaints from ECCE teachers is the lack of resources for teaching. Such a complaint need not be heard again…(i)n the Pacific, where our surroundings are full of natural resources and our communities are caring, we can count ourselves very fortunate. Where children are in need, and teachers and communities have the skills and imagination to invent, there can be no truer saying than necessity is the mother of invention.

A major aspect of the 5-week training that ECCE teachers receive involves learning about construction of preschool buildings and equipment using readily available natural resources. When the key teachers travel to the provinces to conduct training for local teachers, they are accompanied by a builder who will then assist the local teachers and local communities in

building new preschool facilities, where necessary. Teachers also receive training on how to make use of local materials to construct learning materials for the classroom.

Teachers learn how to make a collection of materials using natural resources (including natural dye for colors). Ongoing supervision is provided to teachers by local and national ECCE key teachers, who make regular visits to preschools.

Reaching the Unreachable: Mobile Early Childhood Care and Development Programs in the Philippines

The Philippines has a well-developed system of ECCE provision, due partly to its enactment of the Early Childhood Care and Development (ECCD) Law in 2000, which required the establishment of a National Coordinating Council for the Welfare of Children. A major focus for the Philippines, in line with EFA goals, is to increase access to ECCE programs to children in remote and conflict-affected communities. Organizations and groups working in the Philippines have therefore focused on developing innovative solutions to challenges associated with access. Among these is a 'mobile resource center,' implemented in the Philippines in 2005. The resource center consists of a roving vehicle (horses are also widely used in hard-to-access regions) driven by an ECCE worker equipped with learning materials, manipulative toys, musical instruments, health and nutrition education materials, and supplies. According to UNICEF reports, the ECCE worker is trained in ECCE, uses a curriculum adopted in national day care services, and is paid for by Local Government Units (F. Nogra-Abog, personal communication, 7 November 2010) (Box 2).

Box 2 Mobile Playgroups in Hard-to-Access Regions of the Philippines Extracted from Nogra-Abog, F., 2010. Reaching the Unreached: Alternative Ways of Delivering Early Childhood Education in the Philippines. (Powerpoint slides). UNICEF, Philippines. Extracted from Nogra-Abog, F., 2010. Reaching the Unreached: Alternative Ways of Delivering Early Childhood Education in the Philippines. (Powerpoint slides). UNICEF, Philippines.

This service has provided children with the opportunity to play, socialize, and learn. It provided a safe place while parents are at work. It became the venue where children were able to access basic health services. The parent education services, on the other hand, have increased their awareness on proper childcare. They assist the ECCD workers by helping produce indigenous materials and integrate cultural poems, songs, and dances in the daily activities. The appreciation of parents and children overwhelmed and boosted the morale of community leaders. It also made them realize the need to increase basic services in their communities. Experience from this initiative shows that alternative early childhood education services are effective in reaching the unreached and that community leaders are able to provide and sustain innovations if 'shown the way.' Key to this is demonstrating that the innovation is workable, effective, and affordable. Affectionately known as 'ECCD-on-horse' (the Philippines prefers to incorporate the 'd' for development rather than education in its conceptualization of early childhood programs), the mobile resource center is specifically aimed at providing ECCE services to children in the four remote and conflict-affected communities of Buldon and South Upi in the province of Maguindanao. These communities are characterized by extreme poverty, absence of basic services, rugged and mountainous terrain, and sporadic occurrence of clan wars and armed conflict between the military and rebels. The vehicle/horse visits the same 10 communities at least 3 times a week for 10 consecutive weeks. After leading play and learning activities with children, facilitators meet with parents to conduct parenting sessions on life-saving and effective parenting information. The program, which is designed to fit with a holistic approach to ECCE, also serves as an entry point for delivering other services such as supplementary feeding, vaccinations, as well as physical and dental examinations, all funded by Local Government Units (F. Nogra-Abog, personal communication, 7 November 2010).

Mobile ECCD programs were also initiated in Davao City, with support from the Australian Government Overseas Aid Program in late 2008. By June 2009, the two mobile ECCD programs of Davao City were expected to have reached a minimum of 1000 children from 26 of the most depressed and densely populated communities in Davao City. Formal assessments of quality in mobile ECCD services have not as yet been conducted, due in part to a lack of availability of relevant, conceptually grounded, or validated tools. However, in terms of quantity, they have reached a total of 7241 children in less than 2 years of implementation and have yielded positive anecdotal feedback.

According to initial assessments conducted by UNICEF (Nogra-Abog, 2010), the mobile programs have provided children with valuable opportunities to play, socialize, and learn, as well as a safe place to be cared for while parents are at work. The integrated nature of these services has led to increased access to basic health services, increased parental awareness about appropriate childcare, and increased parental involvement in programs. For example, parents have assisted ECCD program facilitators by helping to produce indigenous materials and integrate cultural poems, songs, and dances in the programs' daily activities. The enthusiasm of parents and children has resulted in ripple effects in local communities, where community leaders have been motivated to commit to increasing basic services in their communities. Nogra-Abog (2010) notes that a key outcome of these programs has been acknowledgment of the importance of innovative approaches to providing childhood education services for effective efforts in reaching children who are living in communities where access has presented challenges, and also, that community leaders are eager to contribute to and sustain innovations if "presented with workable 'tools'." Key to this is demonstrating that an innovation is pragmatic, effective, and affordable.

This snapshot of programs designed specifically to provide access to ECCE programs for children in 'unreached'

communities (a focus of many countries around the world regions currently, as reflected in the Moscow Framework for Action) provides an illustration of the limitations in measures of quality currently supported in international literature. Such measures tend to assume that children attend programs that are located in a permanent physical structure and offer curricula designed to support the development of specific skills/learning dispositions (Fenech, 2011; Pearson, 2011). A number of recent publications have hence called for the development of more nuanced measures that support contextually based approaches to defining quality programming for young children with varied needs across diverse contexts (Myers, 2004; Woodhead, 2006).

Lessons from Djibouti: Grandmothers Promote Exclusive Breastfeeding as the Key Communication Actors

ECCE, as defined by UNESCO (2006), refers to the period from birth to 8 years of age. Although ECCE policies tend to cater to children older than 3 years, in many countries, there is increasing focus not only on infants and toddlers but also on further acknowledgment of the importance of pre- and perinatal care as part of ECCE (Engle et al., 2007). Involving parents and communities, as well as providing more formalized interventions in supporting early development and learning, has therefore become increasingly important.

In order to improve breastfeeding rates in Djibouti, community-based programs for awareness raising were implemented in 2007. Prior to program intervention, qualitative research was conducted in order to identify (1) factors linked to low breastfeeding rates and (2) 'key actors' likely to be able to influence new mothers. Based on results from the study, grandmothers were invited to participate in the program as trainees and, subsequently, trainers, in order to solve issues around social norms and values that might impede breastfeeding.

As part of the program, grandmothers (initially 11, but ultimately 156 in total) received training from nurses and staff at the Ministry of Health. Training was delivered through the use of pictures and alternative materials to overcome literacy barriers. Trained grandmothers then provided support and training to mothers through group sessions and home visits to mothers of children younger than 5 years. In addition, communication materials were developed with involvement from grandmothers (including songs and theater shows) and broadcast through national radio.

UNICEF reports that although breastfeeding rates remain relatively low in Djibouti, this intervention program has resulted in significant increases in breastfeeding (25% from just over 1% before 5 years). The program is also used to promote a 'Communication for Development' approach to working with communities, where it is often found that involving key community members in communicating health-related messages can significantly enhance the impact of social mobilization activities.

Summary

These snapshots of ECCE-related programs and initiatives currently being implemented across the world regions provide a glimpse into the rich diversity in programming that exists in the increasingly globalized world of ECCE. They also reflect growing awareness that, in order to address some of the key challenges and goals that have been outlined by representatives from across the world regions in the Moscow Framework for Action, innovative solutions are required to resolve complex challenges in providing ECCE to all children. Each 'case' also highlights the importance of reaching out to and involving communities in ECCE, particularly in establishing programs where financial resources may be constrained.

As a number of well-respected international experts in the field of ECD and education have argued, understandings of what is 'best' for children vary based on local customs, resources, family and political structures, values, and beliefs (Nsamenang, 2009; Woodhead, 2006). The range of opportunities for innovation through discovery and development of existing resources, both human and otherwise, (1) to define 'quality' in ECCE and (2) to put in place quality programs that support children, their families, and communities represents one of the most exciting aspects of ECCE in the present time.

The implications, however, in terms of developing policies that adequately respond to national and community needs, as well as ensuring high quality through monitoring and assessment for ECCE across the world regions, are challenging. There can be no question that quality in ECCE provision is paramount, both for the well-being of young children and if investments are to result in significant returns in the form of well-prepared and productive future citizens. However, current approaches, tools for assessment, and understandings of what is 'best' for young children are dominated by an 'international' body of scholarly literature that reports largely on research conducted in Western Europe and North America (Fenech, 2011). Of considerable value to developments in ECCE across the world regions, therefore, would be greater proliferation, acknowledgment, and dissemination of rigorous, research-based evidence to support the development of diverse ECCE programs that respond to varied priorities and circumstances.

Conclusions

As we move toward the middle of this 'new' century, ECCE policies and programs across the world regions are faced with both exciting opportunities and formidable challenges. There is shared global agreement about contemporary priorities (reflected in the Moscow Framework For Action and Cooperation), as well as increased acknowledgment of the need for 'localized' approaches to uphold principles of access and equity.

With increased focus on ensuring high-quality provision in programs that support young children and their families/communities, there are opportunities for innovation and knowledge sharing across the world regions. It is important, however, that such sharing is clearly representative of diverse experiences and priorities, avoiding widespread domination of ECCE constructs, tools, and ideals that emanate from particular world regions (Nsamenang, 2009). For example, given the current global expansion of focus in ECCE and, importantly, increased attention to the role of cultural sustainability in young children's learning development, efforts to build and

uphold quality in formalized ECCE do require a more truly globalized evidence base. As Myers (2006: p. 31) indicates:

> If the characteristics and processes of an educational environment are not consistent with the kind of world, country and citizenry desired, as set out in national documents and curricula, and/or with widely agreed-upon rights for children, it is difficult to say that the program is of high quality.

To return to the opening quote, now is the time for supporting the positive development and learning of young children across the world regions. It is also the time for protecting children's long-term livelihoods by ensuring that the formalized programs put in place to provide such supports also uphold wider principles associated with sociocultural sustainability and community development.

Early Emotional Development and Cultural Variability

Fantasy T Lozada, University of Michigan, Ann Arbor, MI, USA
Amy G Halberstadt, North Carolina State University, Raleigh, NC, USA

© 2015 Elsevier Ltd. All rights reserved.

Abstract

The goal of this article is to consider how culture impacts the nature of early emotional development. First, we review broad developmental trajectories of emotional development through the integration of biological and social system changes, embedded in the context of culture. Second, we discuss several cultural frameworks with which to examine cross-cultural comparisons of emotional development and how these frameworks impact parental socialization strategies and subsequent emotional outcomes in infancy and early childhood. Throughout, we review recent empirical work that supports the manifestation of cross-cultural similarities and differences in early emotional development.

Introduction

Emotion is a complex yet integral part of the human experience. Individuals' emotions and those of others around them are salient in reactions to everyday experiences, motivations toward specific behaviors, and engagement with others. Furthermore, the development of emotion is intertwined with other important systems, including those associated with physiological, cognitive, and social change. For infants and young children, emotional competence is an important achievement, yet the expectations about and emphasis on emotional competence are embedded within the beliefs and norms of the cultural, social, and physical structures in which children are raised. This article considers the nature of emotional development in infancy and early childhood in the context of culture. When we refer to emotional development, we are thinking of a dynamic, tripartite system comprised of emotional experience, emotional expression, and emotion understanding; these also have reverberating effects upon each other and across other systems (Halberstadt et al., 2001). Emotion experience and expression appear indistinguishable at birth, but over the first year of life can begin to diverge as infants become aware of the expectations of others and also attempt to influence those others. For the sake of brevity, we will discuss emotional experience and expression together, except when noting research that is able to differentiate their trajectories.

The Underpinnings of Emotional Development

Emotional development is predicated on both biological and social system changes, which are themselves intertwined. Specifically, rapid postnatal development of brain structures (e.g., the limbic system, brain stem, and prefrontal cortex) and hormonal influences contribute to the activation and regulation of emotion expression. Throughout the first few years of life, brain structures such as the cerebral cortex develop and exert increasing control over and sometimes affect change in the limbic system, resulting in fewer mood swings and greater emotional regulation. The young child's increased sophistication in emotional communication and regulation is evidence of the emergence of these biological brain systems (see Easterbrooks et al., 2013, for a review).

The biological changes that support emotional development also occur in the context of developing caregiver–child social relationships in which the majority of early childhood emotional experiences occur. For example, infant distress may be expressed to get a caregiver's attention and to get needs met; once recognized, negative emotions may be met with caregiver attempts to soothe or comfort the child. Infant experiences of positive emotions occur during interactions such as feeding time, soothing, and close physical contact between the caregiver and child. This pattern of emotional sensitivity and responsiveness in parenting results in secure parent–child attachment, which is thought to be important for socioemotional competencies throughout childhood. Infants' early social environment also contributes to their neurobiological development and organization. For example, infants who are at genetic risk for poor emotion regulation may have worse outcomes when raised in a nonsupportive and nonresponsive family environment than infants who are either not at genetic risk or who are at genetic risk but are raised in more supportive family environments. Interestingly, because genetic risk may also be associated with greater sensitivity to the influence of the social environment overall, infants who are at genetic risk may actually have the most favorable outcomes in comparison to other children when they are placed in positive family environments with caregiver sensitivity and secure caregiver–child attachment (Easterbrooks et al., 2013).

In addition to the transactions between infants' and young children's social environments and neurobiological development, infants and young children are effecting changes in their social environments. For example, infants' emotional behavior provides feedback to caregivers about the efficacy of the caregivers' strategies in achieving their goals, which are, of course, developed within cultural contexts. For example, although caregivers tend to be universally interested in reducing infant distress, some cultures may emphasize the importance of reducing distress to a greater extent than others. That is, some cultures may emphasize immediate responses to distress based on that culture's belief that negative affect is not good to experience for extended periods, whereas other cultures may consider distress as a part of life and parents in that culture may

 http://dx.doi.org/10.1016/B978-0-08-097086-8.23007-9

respond less quickly so that children can practice self-soothing or regulation. Within these contexts, caregivers learn from infants' emotionality regarding the success of their strategies in reducing current distress and/or avoiding similar instances in the future. In this way, the infant and the culture work together to scaffold caregiving responses.

Emotional Development Trajectories

Emotional Experience and Expression

Research on the development of emotional experience focuses on two types of broad emotional categories: primary or basic emotions (e.g., happiness, sadness, anger, fear, disgust, and surprise) which appear in both humans and some animals and self-conscious or self-in-relation emotions (e.g., jealousy, embarrassment, pride, shame, guilt, and empathy) and those which require advanced cognition about the self in relation to others. Although basic emotions are assumed to be universal, only broad emotional reactions are thought to be present at birth. Instead, maturational shifts in biological brain functioning and increases in attention and subsequent organizational and interpretive skill in assessing the environment facilitate the emergence of the basic emotions throughout the first year of life. Although researchers have thought previously that emotions rely entirely on maturational aspects, given that elements of joy, sadness, anger, and disgust are reported to appear around 3 months, recent reviews suggest that prototypical expressions of these emotions develop slowly over the first year of life (Camras and Shutter, 2010; Halberstadt et al., 2013). Because infants are also beginning during this time to understand the norms of their social world, their expression of even basic emotions may reflect the norms of their culture. This question remains largely untested with infants and children, with geographic 'dialects' in emotion expression only recently identified in adults (Elfenbein, 2013). The more cognitively complex emotions that consider the self in relation to others, such as jealousy, embarrassment, shame, pride, and guilt, emerge later in the second year of life, and may be even more subject to cultural influence.
